## Table of Contents

LIST OF FIGURES .....  1
LIST OF TABLES ..... VI
ACKNOWLEDGEMENTS ..... VII
EXECUTIVE SUMMARY ..... VIII

1. INTRODUCTION ..... 1
1.1 BACKGROUND .....  1
1.2 Motivation ..... 6
1.3 SCOPE OF STUDY ..... 6
1.4 GOALS .....  8
2. WHERE DO GREAT SALT LAKE DUST PLUMES ORIGINATE? ..... 9
2.1 Methodology ..... 9
2.2 Soll Texture Analysis ..... 14
2.3 SURFACE CRUST TyPES ..... 17
2.4 Testing for Dust Plumes by Manually Disturbing the Surface ..... 25
2.5 Vegetation ..... 25
2.6 DUST "Ноt SpOts". ..... 29
2.7 Key Findings/Uncertainties ..... 29
3. HOW COMMON ARE STRONG WIND EVENTS? ..... 32
3.1 Available Data ..... 32
3.2 Previous Research ..... 33
3.3 Climatology of Strong Wind Events Along the Wasatch Front ..... 34
3.3.1 Wind Rose Analysis ..... 34
3.3.2 Strong Wind Conditions ..... 36
3.3.3 Meteorological Drivers of Observed Wind Regimes ..... 39
3.4 Key Findings/Uncertainties ..... 39
4. DO DUST PLUMES FROM THE GSL CONTAIN HARMFUL HEAVY METALS? ..... 41
4.1 Methodology ..... 41
4.2 EPA Regional Screening Levels. ..... 43
4.3 PM 10 Elemental Mass Fractions ..... 44
4.3.1 Elements Without Health Standards ..... 47
4.3.2 Elements Below Health Standards ..... 52
4.3.3 Elements Exceeding Residential RSLs ..... 55
4.3.4 Elements Exceeding Industrial RSLs ..... 56
4.4 Key Findings/Uncertainties ..... 56
5. HOW WILL LAKE ELEVATION FLUCTUATIONS IMPACT DUST PRODUCTION? ..... 58
5.1 Methodology ..... 58
5.2 Visible Fines Elevation Distribution ..... 60
5.3 DUSt "Нот Spot" Elevation Distributions ..... 61
5.4 Effects of Lake Elevation Fluctuations on the Number of Dust "Hot Spots" ..... 63
5.5 Key Findings/Uncertainties ..... 67
6. HAVE HUMAN ACTIVITIES ALTERED THE CHEMICAL COMPOSITION OF GSL SURFACE SOILS? ..... 68
6.1 Results ..... 68
6.2 Key Findings/Uncertainties ..... 74
7. REFERENCES ..... 75
APPENDIX A: MAPS SHOWING THE LOCATIONS OF ALL THE SUB UNITS. ..... 77
APPENDIX B: FINE (SILT + CLAY) FRACTIONS FOR EACH SUB UNIT ..... 84
APPENDIX C: SURFACE CONDITION OBSERVATIONS OF THE GSL PLAYA ..... 85
APPENDIX D: MAPS SHOWING THE AREAS OF THE GSL PLAYA WHICH GENERATED DUST PLUMES WHEN MANUALLY DISTURBED ..... 216
APPENDIX E: MAPS SHOWING THE AREAS OF THE GSL PLAYA WHERE VEGETATION WAS OBSERVED ..... 224
APPENDIX F: MAPS SHOWING THE GSL DUST "HOT SPOTS" ..... 232
APPENDIX G: PM 10 ELEMENTAL MASS FRACTION DATA ..... 240
APPENDIX H: MAPS SHOWING THE SPATIAL DISTRIBUTIONS OF THE PM 10 SOIL ELEMENTS ..... 253

## List of Figures

1.1 Satellite images of the Great Salt Lake from December 1984 (top) and December 2016 (bottom) showing the dramatic decrease in the surface area of the lake ..... 2
1.2 Fluctuation in water-surface elevation for Gilbert Bay (south part), Great Salt Lake, 1848 to 2018. (US Geological Survey) ..... 3
1.3 Diagram showing the major inflows and outflows of water to the Great Salt Lake. When Inflow > Outflow the lake level will rise. When Inflow < Outflow the lake level will decrease .....  4
1.4 Temporal changes in water inputs, water use, and elevation of the Great Salt Lake. a) water flow in GSL headwater streams above diversions, b) estimated consumptive use of water for agriculture, salt ponds, wetlands, and cities, and c) observed level of the GSL (red line) with the modelled lake elevation in the absence of consumptive water (blue line) [Source: Wurtsbaugh et al., 2017] .....  .5
1.5 Example of a dust plume from the Great Salt Lake impacting the air quality in downtown Salt Lake City on November 16, 2016. These images were captured from a webcam mounted on the roof of the William Browning Building on the University of Utah campus looking west. The Great Salt Lake is on the right side of the image and the wind was blowing from the north (i.e., right to left). The images were captured at 15:17:40 MDT (top) 15:48:00 MDT (center), and 16:20:18 MDT (bottom), respectively ..... 7
1.6 Example of a dust plume from the Great Salt Lake playa generated by a thunderstorm downdraft. Photo taken on July 30, 2017 on the northern portion of Gunnison Bay directly south of the Locomotive Springs Waterfowl Management Area. View is to the west ..... 8
2.1 Map showing how the Great Salt Lake was divided into 10 Decision Units (DU) for this study .....  .9
2.2 The University of Utah "Dust Devil" bicycle/trailer used in this study (top left). Comparison of the tracks left by an all-terrain vehicle (ATV) and the bicycle/trailer (top right). Damage done to the playa extracting an ATV which had become stuck (bottom) ..... 11
2.3 Lake elevations measured in the northern (top) and southern (bottom) arms of the GSL during the Great Salt Lake Dust Study (Source: US Geological Survey) ..... 12
2.4 Comparison of the percent of soil in each sieve fraction for all of the $A$ and $B$ (surface crust) samples ..... 13
2.5 Histogram of the silt and clay percentages for the entire GSL lakebed ..... 15
2.6 Average percentage of fine material (i.e., silt and clay) in each Decision Unit ..... 15
2.7 Map showing what fraction of the GSL lakebed soil is composed of silt and clay. Actual values for each SU are included in Appendix B. This same color scale is used for the maps contained in Appendix A ..... 16
2.8 Examples of thick crust (top and center) and erodible thick crust (bottom) ..... 18
2.9 Examples of erodible moderate crust ..... 19
2.10 Examples of shallow crust. (Top) Granules on the shallow crust with blowing dust in the background. (Center) Cross-sectional view of the shallow crust. (Bottom) Erodible shallow crust ..... 20
2.11 Examples of no crust (top), no crust with a sand dune (center), and no crust due to disturbance by ATVs (bottom) ..... 21
2.12 Summary of surface crust characteristics for the entire GSL lakebed ..... 22
2.13 Thick crust (TC) and erodible thick crust (ETC) percentages for each DU ..... 23
2.14 Moderate crust (MC) and erodible moderate crust (EMC) percentages for each DU ..... 23
2.15 Shallow crust (SC) and erodible shallow crust (ESC) percentages for each DU ..... 24
2.16 No crust (NC) percentages for each DU ..... 24
2.17 Map showing the locations which passed the boot test and generated visible dust plumes when disturbed. Detailed maps of each DU are contained in Appendix D. ..... 26
2.18 Average total (V) and partial (SV) vegetative cover for each DU ..... 27
2.19 Relationship between the vegetative cover and the fraction of fine particles (i.e., silt and clay) in the soil. ..... 27
2.20 Map showing the locations where vegetation was observed on the GSL lakebed. Red markers indicate that the vegetation occurred in an area where the boot test generated dust plumes from the surface. Detailed maps showing the locations of vegetation in each DU are provided in Appendix E. ..... 28
2.21 Venn diagram identifying dust "hot spots" as the union of NV, VF, and NC/ESC ..... 29
2.22 Map showing the locations of the Great Salt Lake dust "hot spots" (i.e., no vegetation, no crust or an erodible shallow crust). Detailed "hot spot" maps for each DU are provided in Appendix F ..... 31
3.1 Map showing locations of wind observations. A: Salt Lake City International Airport (KSLC), B: Hawthorne Elementary (HW), C: Bountiful (BV), D: Lindon (LN), E: Kennecott Dike (KCCO5), F: Kennecott Center Tailings (KCC13), G: Saltair (QSA). The location of the new Utah State Correction Facility is shown as a red square. [Source: mapper.acme.com.]. ..... 32
3.2 Windrose plots for KSLC, HW, BV and LN. Only data is included when all stations were reporting. Winds below $1 \mathrm{~m} \mathrm{~s}^{-1}$ are excluded from wind statistics. Value n gives the number of 1-minute data points where winds exceed $1 \mathrm{~m} \mathrm{~s}^{-1}$ ..... 35
3.3 Windrose plots for KCC13, KCCO5 and QSA. All available data is included. Value n gives the number of hourly data points where winds exceed $1 \mathrm{~m} \mathrm{~s}^{-1}$. ..... 35
3.4 Windrose plots of high wind conditions for KSLC, HW, BV and LN. Data is included only when all stations were reporting. Winds $<11 \mathrm{~m} \mathrm{~s}^{-1}$ are excluded from the wind statistics. The n value gives the number of 1-minute data points when winds exceed $11 \mathrm{~m} \mathrm{~s}^{-1}$. ..... 37
3.5 Windrose plots of high wind conditions for KCC13, KCCO5 and QSA. All available data is included. The n value gives the number of hourly data points when winds exceed $11 \mathrm{~m} \mathrm{~s}^{-1}$. ..... 37
4.1 Bivariate correlation plots of the ICPMS and normalized SXRF data for the major soil elements not associated with evaporites (i.e., Al, Mn , and Ti ) and the major trace element (Cu). The regression statistics for each bivariate correlation are shown in the upper left corner of the plots ..... 43
4.2 Elemental mass fractions for all of the $\mathrm{PM}_{10}$ soil samples collected from the exposed lakebed of the GSL. The median for each element is identified by a round circle while the interquartile ranges (i.e., between the $25^{\text {th }}$ and $75^{\text {th }}$ percentiles) are indicated by the solid blue boxes. The solid lines indicate $\pm 2.7 \sigma$ (i.e., standard deviation). For a normally-distributed dataset, $\pm 2.7 \sigma$ would encompass $99.3 \%$ of the data. Outliers are shown as small red dots. ..... 46
4.3 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions ( $\mathrm{mg} / \mathrm{kg}$ ) for $\mathrm{Br}, \mathrm{Ca}, \mathrm{Ce}, \mathrm{Cs}, \mathrm{Cl}$ and Dy ..... 47
4.4 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions ( $\mathrm{mg} / \mathrm{kg}$ ) for $\mathrm{Er}, \mathrm{Eu}, \mathrm{Gd}, \mathrm{Ga}, \mathrm{Ho}$, and Lu. ..... 48
4.5 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions ( $\mathrm{mg} / \mathrm{kg}$ ) for $\mathrm{Mg}, \mathrm{Nd}, \mathrm{P}, \mathrm{K}, \mathrm{Pr}$ and Rb . ..... 49
4.6 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions ( $\mathrm{mg} / \mathrm{kg}$ ) for $\mathrm{Sm}, \mathrm{Sc}, \mathrm{Na}, \mathrm{S}, \mathrm{Tb}$, and TI ..... 50
4.7 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions ( $\mathrm{mg} / \mathrm{kg}$ ) for $\mathrm{Th}, \mathrm{Ti}, \mathrm{Yb}$, and Y . ..... 51
4.8 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions ( $\mathrm{mg} / \mathrm{kg}$ ) for $\mathrm{Al}, \mathrm{Ba}, \mathrm{Be}, \mathrm{B}, \mathrm{Cd}$, and Cr ..... 52
4.9 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions (mg/kg) for $\mathrm{Fe}, \mathrm{Pb}, \mathrm{Mo}, \mathrm{Ni}, \mathrm{Se}$, and Si ..... 53
4.10 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions ( $\mathrm{mg} / \mathrm{kg}$ ) for $\mathrm{Ag}, \mathrm{Sr}, \mathrm{U}$, and Zn . ..... 54
4.11 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions ( $\mathrm{mg} / \mathrm{kg}$ ) for $\mathrm{Sb}, \mathrm{Co}, \mathrm{Cu}, \mathrm{Mn}$, and V. ..... 55
4.12 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions ( $\mathrm{mg} / \mathrm{kg}$ ) for $\mathrm{As}, \mathrm{La}, \mathrm{Li}$, and Zr . ..... 56
5.1 Map showing the coverage of the $0.5-\mathrm{m}$ (light blue) and 1-m (dark blue) resolution digital elevation model derived from aircraft LiDAR data collected during the fall of 2016 ..... 59
5.2 Comparison of the LiDAR elevation data with the USGS bathymetric data. ..... 60
5.3 Histogram of the elevations of all the locations with visible fines (VF) ..... 61
5.4 Histogram of the elevations of all the GSL dust "hot spots" ..... 62
5.5 Histograms of the elevations of the GSL dust "hot spots" located in the northern (left) and southern (right) halves of the lake. ..... 62
5.6 The fraction of dust "hot spots" located in Farmington Bay covered by water as a function of GSL elevation. The uncertainty of the GSL elevation measurements is indicated by the red error bars ..... 63
5.7 The fraction of dust "hot spots" located in Bear River Bay covered by water as a function of GSL elevation. The uncertainty of the GSL elevation measurements is indicated by the red error bars ..... 64
5.8 The fraction of dust "hot spots" located in Gilbert Bay covered by water as a function of GSL elevation. The uncertainty of the GSL elevation measurements is indicated by the red error bars ..... 65
5.9 The fraction of dust "hot spots" located in Gunnison Bay covered by water as a function of GSL elevation. The uncertainty of the GSL elevation measurements is indicated by the red error bars ..... 66
6.1 Map showing the spatial distribution of lanthanum ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil ..... 69
6.2 Map showing the spatial distribution of phosphorus $(\mathrm{mg} / \mathrm{kg})$ in the $\mathrm{PM}_{10}$ fraction of the soil ..... 69
6.3 Map showing the spatial distribution of cadmium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil. ..... 70
6.4 Map showing the spatial distribution of lead $(\mathrm{mg} / \mathrm{kg})$ in the $\mathrm{PM}_{10}$ fraction of the soil. ..... 70
6.5 Map showing the spatial distribution of zinc $(\mathrm{mg} / \mathrm{kg})$ in the $\mathrm{PM}_{10}$ fraction of the soil ..... 71
6.6 Map showing the spatial distribution of copper $(\mathrm{mg} / \mathrm{kg})$ in the $\mathrm{PM}_{10}$ fraction of the soil ..... 71
6.7 Map showing the spatial distribution of molybdenum ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil ..... 72
6.8 Map showing the spatial distribution of silver $(\mathrm{mg} / \mathrm{kg})$ in the $\mathrm{PM}_{10}$ fraction of the soil. ..... 72

## List of Tables

1.1 Impact of Water Diversions on GSL Elevation (Wurtsbaugh et al., 2016) ..... 6
2.1 Summary of Incremental Sampling Methodology (ISM) Decision Units (DUs) ..... 10
2.2 Soil Classification System Used in this Study [Based on Wentworth (1922)] ..... 14
2.3 Summary of the Surface Condition Categories Used in this Study ..... 17
3.1 Meteorological Measurement Locations, Time Intervals, and Data Coverage ..... 33
3.2 Summary of high-wind conditions at the selected study locations, illustrating the higher frequency of strong ( $\geq 11 \mathrm{~m} \mathrm{~s}^{-1} ; \geq 9 \mathrm{~m} \mathrm{~s}^{-1}$ ) winds near the new Utah State Correction Facility site, and the dominating southerly winds direction during high-wind events. ..... 38
4.1 Summary of Analytical Techniques Used for this Study ..... 42
4.2 Comparison of the GSL PM ${ }_{10}$ Soil to the Average Abundance of Elements in the Earth's Crust (Taylor and McLennan, 1985) ..... 45
5.1 Comparison of USGS GSL Elevation Data with LiDAR Data. ..... 58
5.2 Summary of GSL Elevation Impact on Dust Mitigation ..... 67
6.1 Coefficient of Variation Data Ordered from the Greatest to the Least Variance ..... 73

## Acknowledgements

We would like to thank the following land owners/managers for providing permission to cross their property to access the exposed playa of the Great Salt Lake:
$388^{\text {th }}$ Fighter Wing Hill Air Force Base Antelope Island State Park

Compass Minerals
Deseret Land and Livestock Promontory Ranch
Morton Salt
National Audubon Society
Rio Tinto Kennecott Utah Copper LLC
Union Pacific Railroad
U.S. Fish and Wildlife Service Bear River Migratory Bird Refuge
U.S. Magnesium LLC.

Utah Department of Natural Resources
Utah Division of Wildlife Resources

The Synchrotron X-ray Fluorescence (SXRF) analysis was performed at the Advanced Light Source (Lawrence Berkeley National Laboratory) with the assistance of Dr. Yongjing Zhao.

The Inductively Coupled Plasma Mass Spectrometry (ICPMS) analysis was performed in the Department of Geology and Geophysics at the University of Utah under the direction of Dr. Diego Fernandez.

Additional support for this project was received from a University of Utah Society, Water, and Climate (SWC) seed grant.

Bicycle maintenance and repair was performed by Salt Cycles Bike Shop (Sandy, UT).
We also wish to provide special thanks to the following individuals:
Ella Sorensen (National Audubon Society) who provided an overview of the habitat and wildlife along the southern shore of the GSL which was quite helpful in the early stages of this project.

Master Sergeant Andrew B. Filcher (USAF AFMC 775 CES/CED) who served as our escort at the Utah Test and Training Range and spent hours digging our ATV out of the playa and returning us safely to the base headquarters.

## Executive Summary

The elevation of the Great Salt Lake (GSL) has recently reached historically low levels due to a combination of water diversion and drought. Due to the shallow nature of the GSL, more than 750 square miles of lakebed are now exposed. As a result, dust plumes originating from the exposed lakebed have become common. These dust plumes have a significant impact on local air quality and have been shown to reduce the snowpack in the adjacent mountains due to enhanced melt rates. With more than 2 million residents living in close proximity to the GSL, there is also a concern that the dust plumes might pose a health hazard. It is for these reasons that the Utah Department of Natural Resources (Division of Forestry, Fire, and State Lands) and the Utah Division of Facilities Construction and Management funded this study to learn more about the GSL dust plumes.

The specific goals of the Great Salt Lake Dust Plume Study were to:

- Identify the GSL dust source regions (i.e., "hot spots"),
- Determine how frequently strong wind events occur along the Wasatch Front,
- Determine if the $\mathrm{PM}_{10}$ dust from the GSL contains heavy metals which might pose a threat to human health,
- Estimate how fluctuating lake levels might impact future dust production from the GSL, and
- Determine whether the composition of the dust from the GSL has been altered by local anthropogenic sources.

A systematic survey of all 757 square miles of the exposed GSL lakebed was undertaken between June 2016 and August 2018 using Incremental Sampling Methodology (ISM). Following ISM protocols, the lakebed was divided into 10 Decision Units (DUs) comprised of 122 Sub Units (SUs). Surface crust observations and soil samples from the top 1-2 cm were collected at a total of 5246 locations. Due to the heterogeneous nature of the lakebed, the soil samples from each SU were composited into 122 soil samples which were then dried, sieved, resuspended, and analyzed to determine the elemental mass fractions of the respirable particles (i.e., particles with diameters < $10 \mu \mathrm{~m}-\mathrm{PM}_{10}$ ). A combination of Inductively-Coupled Plasma Mass Spectrometry (ICPMS) and Synchrotron X-ray Fluorescence (SXRF) provided mass fraction measurements for 53 different elements.

GSL dust plume "hot spots" were identified as locations that had visible fine particles which could be easily displaced, had little or no vegetation, and had either no surface crust or an erodible shallow crust. Dust "hot spots" matching these criteria were identified in all four quadrants of the GSL and comprised about $9 \%$ of the total lakebed. $73 \%$ of the lakebed is currently protected from wind erosion by shallow, moderate, or thick surface crusts while $15 \%$ of the lakebed is covered by some vegetation. If all of the protective crusts were destroyed by human activities or natural erosion, the dust "hot spots" would increase to a maximum of $22 \%$ of the exposed lakebed. On average, the GSL lakebed is composed of $95 \%$ sand and $5 \%$ silt and
clay. It is the areas of the lakebed which have higher silt and clay fractions which are most susceptible to wind erosion.

A review of 10 years of meteorological data from stations near the GSL revealed several weather patterns associated with high wind events. These weather patterns include: prefrontal southerly flow, postfrontal northwesterly flow, easterly downslope windstorms, and outflows from thunderstorms. On average, high wind events (i.e., $\geq 11 \mathrm{~m} \mathrm{~s}^{-1}$ ) near the GSL occurred on 44 days every year totaling about $1.1 \%$ of all observations. This value should be viewed as an upper bound for exposure to GSL dust plumes (assuming that $11 \mathrm{~m} \mathrm{~s}^{-1}$ is an appropriate threshold wind velocity) because the creation of dust plumes requires both strong winds and dry soil conditions.

The $\mathrm{PM}_{10}$ soil from the GSL lakebed is highly enriched in elements associated with evaporite minerals (e.g., boron, calcium, chlorine, lithium, magnesium, sulfur, and strontium). Of the 53 elements measured using ICPMS and SXRF, only nine had some values which exceeded the Residential Regional Screening Levels (RSLs) established by the U.S. Environmental Protection Agency (EPA). These nine elements included antimony, arsenic, cobalt, copper, lanthanum, lithium, manganese, vanadium, and zirconium. Four of these elements (arsenic, lanthanum, lithium, and zirconium) also had some values which exceeded the Industrial RSLs established by the EPA. Elements which exceed the RSLs do not necessarily pose a health risk to adjacent populations because the exposure frequency used in the RSL calculations is extremely conservative. To determine the actual health risk, a site-specific exposure assessment for these nine elements should be performed. It should also be noted that this study did not investigate the impact of GSL dust plumes on the local $\mathrm{PM}_{10}$ or $\mathrm{PM}_{2.5}$ concentrations. Exposure to these criteria air pollutants could pose a health risk independent of the individual particulate matter constituents if the ambient concentrations exceed the National Ambient Air Quality Standards (NAAQS) established by the EPA.

The locations of all the GSL dust "hot spots" were combined with a digital elevation model (DEM) derived from aircraft LiDAR measurements to determine how fluctuations in the lake elevation might impact dust production. It was determined that the number of dust "hot spots" varies linearly with lake elevation in all quadrants of the GSL. The number of dust "hot spots" in Farmington Bay will be reduced by $13.8 \%$ per foot for lake elevations above 4195 ft . The number of dust "hot spots" in Bear River Bay will be reduced by $12.8 \%$ per foot for lake elevations above 4200 ft . The number of dust "hot spots" in Gilbert Bay will be reduced by $11.7 \%$ per foot for lake elevations above 4196 ft . The number of dust "hot spots" in Gunnison Bay will be reduced by $7.3 \%$ per foot for lake elevations above 4197 ft . The GSL elevation is currently so low that further reductions are unlikely to increase the number of dust hot spots in Farmington, Bear River, or Gunnison Bays. However, the number of dust "hot spots" in Gilbert Bay will likely increase at a rate of $11.7 \%$ per foot of lake decline. It should be noted that the number of dust "hot spots" may increase over time independent of lake levels if the protective surface crusts are destroyed by human activity or erode naturally over time.

The spatial variability of the $\mathrm{PM}_{10}$ soil elemental mass fractions was used to infer the presence or absence of significant anthropogenic contamination of the GSL lakebed. The elements with the greatest spatial variability included copper, sulfur, silver, phosphorus, chlorine, molybdenum, zirconium, and lead. Four of these elements (e.g., copper, silver, molybdenum, and sulfur) peaked in the area immediately north of the Kennecott Utah Copper (KUC) tailings pile located on the south shore of the GSL. Elevated phosphorus concentrations in Bear River and Farmington Bays most likely result from fertilizer runoff. Live-fire activities at the Utah Test and Training Range (UTTR) on the western side of the GSL have elevated both the phosphorous and zirconium concentrations in the adjacent lakebed. Several elements including antimony, cadmium, chromium, lead, selenium, and zinc peaked in Farmington Bay. The elements with the most uniform concentrations included barium, magnesium, uranium, calcium, cobalt, selenium, arsenic, zinc, antimony, and lithium.

## 1. Introduction

### 1.1 Background

History has shown that the combination of climate change, drought, and water diversion can quickly reduce once thriving lake ecosystems to a fraction of their former sizes. Recent examples include the Aral Sea, Lake Chad, Lake Urmia, Lake Poopo, Owens Lake, and the Dead Sea. As these water bodies dried up, entire ecosystems were disrupted, industries were shuttered, economies were threatened, new pollution sources (i.e., dust plumes) were created, and local populations suffered.

Most of these lakes were unintentionally depleted in a similar pattern. Drought conditions and increasing local populations put additional pressure on existing water resources resulting in increased water diversion (often for agricultural purposes). This water diversion resulted in a significant, but reversible, decrease in lake levels. Unfortunately, local governments failed to take corrective action in time and the lake ecosystems were destroyed. Once a lake has dried up, the dependent species disappear and the local hydrological cycle is disrupted. Less precipitation in the watershed makes it very hard to reverse the trend and restore the lake to its previous water levels. Worse yet, the dependent species are likely to remain absent for decades even if the lake levels are restored.

Owens Lake, in California, is the only one of the aforementioned lakes which was intentionally desiccated. The City of Los Angeles, which owned the water rights, diverted all of the water on purpose to meet the needs of its growing population. As a result, Owens Lake dried up completely in 1926. Shortly thereafter, Owens "dry" Lake became the largest source of PM ${ }_{10}$ pollution in North America. As it turns out, the fine silt located on the exposed lakebed was easily erodible due to the dry conditions and strong winds that commonly occur on the lee side of the Sierra Nevada Mountains. To make matters worse, chemical composition measurements of the dust plumes originating from the exposed portions of the lakebed showed that the particulate matter contained very high concentrations of arsenic. This posed an unanticipated health hazard to downwind residents above and beyond those associated with $\mathrm{PM}_{10}$ concentrations that drastically exceeded the National Ambient Air Quality Standards (NAAQS) established by the U.S. Environmental Protection Agency (EPA) to protect human health. To date, the City of Los Angeles has spent more than $\$ 1.3$ billion dollars on dust mitigation but has not yet managed to eliminate the problem.

With the Great Salt Lake (GSL) at historically low levels (Figs. 1.1 and 1.2) and additional water diversion projects under consideration (e.g., Bear River Development Project), residents along the Wasatch front are becoming increasingly concerned about the future of the lake ecosystem. The GSL provides crucial habitat for migratory birds, supports the brine shrimp and mineral extraction industries, and provides extensive recreation opportunities for boaters, bikers, birders, hikers, and hunters. Altogether, it is estimated that the GSL provides approximately $\$ 1.32$ billion in economic benefits to the State of Utah annually. As the lake level continues to drop, it exposes more lakebed which increases the likelihood that residents along the Wasatch Front will be exposed to potentially unhealthy concentrations of $\mathrm{PM}_{10}$ and $\mathrm{PM}_{2.5}$ originating from wind-blown dust.

Figure 1.1 Satellite images of the Great Salt Lake from December 1984 (top) and December 2016 (bottom) showing the dramatic decrease in the surface area of the lake.

Figure 1.2 Fluctuation in water-surface elevation for Gilbert Bay (south part), Great Salt Lake, 1848 to 2018 (US Geological Survey: https://waterdata.usgs.gov/ut/nwis/annual?referred module=sw\&search site no=10010000\&format=sites selection links).

The Great Salt Lake Basin includes much of Utah, parts of southeastern Idaho, southwestern Wyoming and eastern Nevada. The GSL, which drains approximately $55,000 \mathrm{~km}^{2}\left(21,445 \mathrm{mi}^{2}\right)$, is the largest terminal lake within the Great Salt Lake Basin. The elevation of the GSL is controlled by the ratio of the inflow to the outflow (Fig. 1.3). The primary inflows are from the Bear, Weber and Jordan rivers. Together, these rivers provide an average of 2 million acre-feet of water annually to the GSL. Additional inflow pathways include direct precipitation and groundwater discharge. As a terminal lake, there are no stream outlets for the GSL and the primary outflow is through evaporation. Additional outflow pathways include groundwater recharge and pumping for mineral extraction. Figure 1.2 shows that the long-term trend (1850present) in GSL elevation is -0.5 ft per decade.

Figure 1.3 Diagram showing the major inflows and outflows of water to the Great Salt Lake. When Inflow > Outflow the lake level will rise. When Inflow < Outflow the lake level will decrease.

A common misperception is that the long-term reduction in the GSL elevation is due to changes in precipitation patterns. A study completed by researchers at Utah State University (Wurtsbaugh et al., 2017) examined the mean stream flow of the Bear river and one of its main tributaries using a combination of tree-ring estimates and direct stream-gauge measurements. Their analysis indicated that there has been no long-term (i.e., 1850 - present) stream flow decreases in the Bear river drainage at locations above existing water diversion structures (Fig. 1.4a). Thus, the long-term decreasing trend in the GSL elevation (Fig. 1.2) cannot be explained by precipitation decreases in the Bear River drainage basin. Wurtsbaugh et al (2017) also estimated the consumptive use of water for agriculture, salt ponds, wetlands and cities (Fig. 1.4b) to determine the net impact of water diversions on the GSL elevation (Fig. 1.4c). Their analysis revealed that, in the absence of water diversion, there would be no long-term decrease in the GSL elevation and that the mean natural elevation of the GSL is 4207 ft . They concluded that consumptive water uses have lowered the lake by 11 ft and decreased its volume by $48 \%$ relative to the mean natural elevation. Table 1.1 shows how each type of water diversion contributed to the GSL elevation decrease. The current GSL elevation ( $\sim 4192 \mathrm{ft}$ as of December 2018) is 15 ft lower than the mean natural elevation of 4207 ft . Thus, the Wurtsbaugh et al. (2017) analysis attributes almost $\sim 75 \%$ of this decrease to water diversion with the remaining ~25\% due to short-term precipitation fluctuations. Wurtsbaugh et al. (2017) goes on to conclude that water diversions must decrease by $24-29 \%$ in order to stabilize the GSL elevation and stop the long-term downward trend shown in Figure 1.2.

Figure 1.4 Temporal changes in water inputs, water use, and elevation of the Great Salt Lake. a) water flow in GSL headwater streams above diversions, b) estimated consumptive use of water for agriculture, salt ponds, wetlands, and cities, and c) observed level of the GSL (red line) with the modelled lake elevation in the absence of consumptive water (blue line) [Source: Wurtsbaugh et al., 2017]

Table 1.1 Impact of Water Diversions on GSL Elevation (Wurtsbaugh et al., 2016).

| Water Diversion Purpose | Percent Water Diversion | Estimated Effect on Lake Level |
| :---: | :---: | :---: |
| Agriculture | $63 \%$ | -7.0 ft |
| Mineral Extraction | $13 \%$ | -1.4 ft |
| Municipal \& Industrial | $11 \%$ | -1.3 ft |
| Impounded Wetlands | $10 \%$ | -1.1 ft |
| Reservoir Evaporation | $3 \%$ | -0.3 ft |

### 1.2 Motivation

Dust plumes originating from the exposed lakebed (i.e. playa) of the GSL have increased in frequency and severity over the last decade as the lake has receded. These dust events are most commonly initiated by strong winds associated with the passage of a cold front (Fig. 1.5), but can also result from thunderstorm downdrafts (Fig. 1.6). Smaller amounts of dust can be lofted by whirlwinds known as dust devils which are common during hot and dry conditions. The images shown in Figure 1.5 demonstrate how severely the air quality in Salt Lake City can be impacted by GSL dust plumes associated with a cold frontal passage. In this example, which took place during the afternoon of November 16, 2016, visibility was reduced to less than 4 miles at the Salt Lake City International airport. In addition, the 24-hr averaged PM ${ }_{10}$ concentration measured at the Utah Division of Air Quality (DAQ) site at Hawthorne Elementary School in Salt Lake City was $66 \mu \mathrm{~g} \mathrm{~m}^{-3}$ even though the dust event only lasted a few hours.

Even though the exposed lakebed of the GSL is recognized as a potentially significant local/regional dust source, little research has been conducted to quantify the air quality impacts or to characterize the specific meteorological conditions and threshold wind velocities capable of lofting the dust. In addition, the specific source regions within the expansive playa have not yet been identified through a systematic survey of the soil surface characteristics and particle size distributions. Without these types of information, it is extremely difficult to accurately model past dust episodes or to predict the occurrence of future dust plumes. More disturbing is the fact that we do not know the chemical composition of the dust that is currently being lofted from the GSL playa. Without chemical composition and accurate $\mathrm{PM}_{10}$ measurements of the GSL dust sources, estimating the potential health impacts is impossible. Managers of the GSL need the types of information described above to make informed decisions which balance the needs of the stakeholders and the health of the two million people living adjacent to the lake.

### 1.3 Scope of Study

The Great Salt Lake Dust Plume Study was jointly funded by the Utah Department of Natural Resources (DNR) and the Utah Division of Facilities Construction and Management (DFCM). However, the two state agencies had very different motivations. The DNR was seeking information about the dust sources which could be used for informed management decisions. The DNR was also curious whether the mineral dust from the GSL contained heavy metals at concentrations which could be potentially harmful to adjacent populations. On the other hand, the DFCM wanted to know if dust from the GSL transported to the new Utah State Correction Facility site (on the south shore of the GSL west of the SLC airport) posed a hazard unique to the site.

Figure 1.5 Example of a dust plume from the Great Salt Lake impacting the air quality in downtown Salt Lake City on November 16, 2016. These images were captured from a webcam mounted on the roof of the William Browning Building on the University of Utah campus looking west. The Great Salt Lake is on the right side of the image and the wind was blowing from the north (i.e., right to left) after the passage of a cold front. The images were captured at 15:17:40 MDT (top) 15:48:00 MDT (center), and 16:20:18 MDT (bottom), respectively.

### 1.4 Goals

The specific goals of the Great Salt Lake Dust Plume Study included:

- Identifying the GSL dust source regions (i.e., "hot spots"),
- Determining how frequently strong wind events occur along the Wasatch Front,
- Determining if the $\mathrm{PM}_{10}$ dust from the GSL contains heavy metals which might pose a threat to human health,
- Estimating how fluctuating lake levels might impact future dust production from the GSL, and
- Determining whether the composition of the dust from the GSL has been altered by local anthropogenic sources.

## 2. Where Do Great Salt Lake Dust Plumes Originate?

### 2.1 Methodology

To determine the dust source regions, a systematic survey of the entire exposed GSL lakebed was undertaken using Incremental Sampling Methodology (ISM).
"ISM is a structured composite sampling and processing protocol that reduces data variability and provides a reasonably unbiased estimate of mean contaminant concentrations in a volume of soil targeted for sampling. ISM provides representative samples of specific soil volumes defined as decision units (DUs) by collecting numerous increments of soil (typically 30-100 increments) that are combined, processed, and subsampled according to specific protocols." (Interstate Technology \& Regulatory Council, 2012)

The total surface area of the exposed portions of the GSL lakebed is very sensitive to the lake elevation but was $\sim 750 \mathrm{mi}^{2}$ at the conclusion of this study when the lake elevation was 4192 ft . Due to the extremely large size of the survey area, the GSL was divided into 10 Decision Units (DUs) (Fig. 2.1). Each of these DUs were further subdivided into Sub Units (SUs) with an average size of $\sim 6 \mathrm{mi}^{2}$ (Appendix A). A total of 122 SUs were sampled for this study (Table 2.1)

Figure 2.1 Map showing how the Great Salt Lake was divided into 10 Decision Units (DUs) for this study.

ISM dictates that each SU be divided into a grid with 30-100 samples per SU. The grid spacing for each DU was chosen to ensure that the minimum number of 30 samples were collected, on average, in each SU. Most of the DUs were sampled with a grid spacing of 500 m . However, the grid spacing in the smallest and largest DUs (i.e., DU1 and DU9) had to be adjusted to 250 m and 750 m , respectively to maintain consistency in the average number of samples per SU. Using a predetermined grid to identify the GPS coordinates of each soil sample prior to collection minimized selection bias. Information bias was minimized by having one individual (Dr. Kevin Perry) collect all of the soil samples and surface crust observations for this study.

To minimize the disturbance of the surface crust, all but one of the SUs were sampled using a bicycle/trailer system (Fig. 2.2). The only exception was the portion of the GSL lakebed within the boundaries of the Utah Test and Training Range (UTTR). The UTTR is a military training facility for air-to-air combat, air-to-ground inert and live practice bombing, and gunnery training by Department of Defense aircrews. The possibility of encountering unexploded ordinance necessitated a military escort and sample collection using an all-terrain vehicle (ATV). Figure 2.2 clearly shows that ATV travel on the playa leaves much more noticeable tracks than the bicycle/trailer system. This figure also shows an example of the significant damage done to the playa in the process of extracting a stuck military ATV. Other advantages of the bicycle/trailer system included its lower cost, a reduced likelihood of getting stuck, and a more nuanced feel for subtle differences in surface crust characteristics. The major disadvantages of the bicycle/trailer system were that it was slow, physically challenging, and required at least five, rain-free days prior to sampling.

The fieldwork for the Great Salt Lake Dust Study commenced on June 16, 2016 and concluded on August 8, 2018. The study required 122 trips to the GSL and 2,300 miles on the bicycle. Approximately $10 \%$ of the lakebed (i.e., 230 miles) was not rideable and required pushing the bicycle/trailer through extremely soft and/or muddy conditions. Figure 2.3 shows that the GSL

Figure 2.2 The University of Utah "Dust Devil" bicycle/trailer used in this study (top left). Comparison of the tracks left by an all-terrain vehicle (ATV) and the bicycle/trailer (top right). Damage done to the playa extracting an ATV which had become stuck (bottom).
elevation in the northern and southern portions of the lake varied by approximately 5.25 feet and 3.25 feet, respectively during the 26 -month sampling period. The GSL is physically divided into two halves by the railroad causeway which transects the entire lake from east to west. Although there are breaks in the causeway designed to permit water exchange, the influx of water from the tributary streams (i.e., Bear River, Weber River, and Jordan River) ensures that the elevation in the southern arm of the GSL is always greater than in the northern arm. However, by late 2016 the lake levels had dropped so low that the existing causeway breaks no longer permitted water exchange. Connectivity was reestablished on December 1, 2016 with the construction of a new causeway break causing a rapid increase in the elevation of the northern arm prior to the normal spring run-off.

Figure 2.3 Lake elevations measured in the northern (top) and southern (bottom) arms of the GSL during the Great Salt Lake Dust Study. (Source: US Geological Survey)

Three soil samples were collected at each ISM survey location. Two samples of the surface crust (top 2 cm or less) were collected within 1 m of each other. These were designated as Samples A and $B$ and represent the surface crust, if present. A third, subsurface sample, designated as Sub, was collected from a depth of $2-4 \mathrm{~cm}$. The subsurface samples, which were not analyzed as part of this study, represent the soil that would be exposed to the atmosphere for possible wind erosion if the current surface material/crust is deflated. The A, B, and Sub soil samples from each ISM survey location within a SU were composited into separate 2.5 -gallon, Ziplock bags. The three, composited soil samples from each SU were then returned to the lab at the University of Utah where they were prepped for analysis. Each sample was dried in an oven at $105^{\circ} \mathrm{C}$ (for a period of at least 24 hours), manually disaggregated using a pestle, and sieved in $\sim 1 \mathrm{~kg}$ increments for a period of 1 hour using the following standard mesh sizes: \#4, \#10, \#20, \#40, \#60, \#100, \#140, and \#200. The soil particle size distribution was then determined by weighing each of the sieved size fractions. The particle size distributions for the A and B samples were remarkably similar with a slope, intercept, and correlation coefficient ( $R^{2}$ ) of 0.96, 0.46 , and 0.95 , respectively (Fig. 2.4). The good correlation between the A and B samples indicates that the particle size distributions were relatively homogeneous at the 1 m scale and that the ISM soil collection and analytical procedures did not introduce any biases into the resultant particle size distributions.

Figure 2.4 Comparison of the percent of soil in each sieve fraction for all of the A and B (surface crust) samples.

### 2.2 Soil Texture Analysis

Soil with a high fraction of silt and clay is generally more susceptible to wind erosion than soils primarily composed of sand. The reason for this is that even very fine sand is quickly removed from the atmosphere via gravitational settling. In contrast, silt and clay can be transported long distances because the particles are smaller and gravitational settling velocities are insufficient to quickly remove these particles from the atmosphere. Wentworth (1922) defined sand as particles with diameters between 2 mm and $62 \mu \mathrm{~m}$, silt as particles with diameters between 62 and $4 \mu \mathrm{~m}$, and clay as particles with diameters $<4 \mu \mathrm{~m}$. Particles larger than sand are referred to as pebbles, cobbles, or boulders. Table 2.2 shows how the sieves used in this study correlate with the Wentworth (1922) classification system. The largest sieve (\#4) captured the boulders, cobbles, and most of the pebbles. Sieve (\#10) captured the very fine pebbles (i.e., granules). The rest of the sieves captured various size classifications of sand. Silt and clay particles are those that were small enough to pass through sieve \#200. The fraction of silt and clay (excluding boulders, cobbles, and coarse pebbles) for each SU was determined by dividing the mass of particles passing through sieve \#200 by the sum of the mass of the particles collected on sieves \#10 through \#200. The results from the A and B samples were then averaged to get the final estimates of the fine (i.e., silt and clay) fraction of the soil.

Table 2.2 Soil Classification System Used in this Study [Based on Wentworth (1922)].

| ASTM Sieve Size Number <br> (U.S. Standard) | Lowest Diameter <br> Size Ranges | Classification |
| :---: | :---: | :---: |
| 4 | 4.76 mm | Boulders + Cobbles + Pebbles |
| 10 | 2.00 mm | Very Fine Pebbles (granules) |
| 20 | $840 \mu \mathrm{~m}$ | Very Coarse Sand |
| 40 | $420 \mu \mathrm{~m}$ | Coarse Sand |
| 60 | $250 \mu \mathrm{~m}$ | Medium Sand |
| 100 | $149 \mu \mathrm{~m}$ | Fine Sand |
| 140 | $105 \mu \mathrm{~m}$ | Fine Sand |
| 200 | $74 \mu \mathrm{~m}$ | Very Fine Sand |
| $>200$ | $<74 \mu \mathrm{~m}$ | Silt + Clay |

The results of the particle size analysis revealed that, on average, the GSL lakebed soil samples have a very low silt and clay content (Fig. 2.5). This means that the GSL playa is primarily composed of various size fractions of sand and is, therefore, less prone to wind erosion than many other regional dust sources. The median silt and clay fraction of $3.8 \%$ indicates that $50 \%$ of the soil samples were composed of more than $96.2 \%$ sand. There are, however, several areas of the lakebed with substantial fine material available for dust generation (Figs. 2.6 and 2.7). The highest silt and clay percentages were observed in DU3 (on the eastern side of Farmington Bay in the SE quadrant of the lake), in DU5 (Bear River Bay in the NE quadrant of the lake), and in DU8 (Ogden Bay on the eastern side of the lake). Each of these DUs are located near the mouth of a river (e.g., DU3 = Jordan River, DU5 = Bear River, and DU8 = Weber River). The southern portion of DU2 (south of Antelope Island) also has higher than average amounts of
fine material due to its proximity to the mouth of the Jordan River. Fig. 2.7 also shows that most bayheads have higher percentages of fine material than the remainder of the DU. This is most evident in DU9 (i.e., the extreme NW quadrant of the lake) and to a lesser extent in DU4, DU7, and DU10. There is also an isolated pocket of fine material at the mouth of Goggin Drain (a Jordan River surplus canal) in DU1-SU7.

Figure 2.5 Histogram of the silt and clay percentages for the entire GSL lakebed.

Figure 2.6 Average percentage of fine material (i.e., silt and clay) in each Decision Unit.

Percent Silt \& Clay

Figure 2.7 Map showing what fraction of the GSL lakebed soil is composed of silt and clay. Actual values for each SU are included in Appendix B. This same color scale is used for the maps contained in Appendix A.

### 2.3 Surface Crust Types

While the fraction of fine material in the parent soil is important when assessing the potential of an area to act as a dust source, the presence of surface crusts and/or vegetation can dramatically reduce the amount of dust generation. Certain types of surface crusts and vegetative cover can even eliminate dust production altogether. It is for this reason that the surface conditions were recorded for each of the 5246 ISM soil sample locations. The surface conditions were categorized with respect to vegetation, surface crust, and special features (Table 2.3). Examples of thick crust, erodible moderate crust, shallow crust, and no crust are shown in Figures 2.8-2.11. The surface condition data for all soil sample locations are included in Appendix C .

## Table 2.3 Summary of the Surface Condition Categories Used in this Study.

| Parameter | Code | Description | Criteria |
| :---: | :---: | :---: | :---: |
| Vegetation | V | Vegetated | $>80 \%$ Coverage |
|  | SV | Some Vegetation | $5 \%-80 \%$ Coverage |
|  | NV | No Vegetation | $0 \%$ Coverage |
|  |  |  | Thickness $>1 \mathrm{~cm}$ |
| Crust | TC | Thick Crust | $0.5 \mathrm{~cm}<$ Thickness $<1 \mathrm{~cm}$ |
|  | MC | Moderate Crust | Thickness < 0.5 cm |
|  | SC | Shallow Crust | No Crust |
|  | NC | No Crust | Erodible Thick Crust |

Figure 2.8 Examples of thick crust (top and center) and erodible thick crust (bottom).

Figure 2.9 Examples of erodible moderate crust.

Figure 2.10 Examples of shallow crust. (Top) Granules on the shallow crust with blowing dust in the background. (Center) Cross-sectional view of the shallow crust. (Bottom) Erodible shallow crust.

Figure 2.11 Examples of no crust (top), no crust with a sand dune (center), and no crust due to disturbance by ATVs (bottom).

The surface crust survey revealed that $67.6 \%$ of the GSL lakebed is protected by a shallow crust (SC) (Fig. 2.12). Intact thick (TC) and moderate (MC) crusts protect an additional $5.7 \%$ of the lakebed. The remaining $26.6 \%$ either has no crust (NC) or an erodible crust of variable thickness (e.g., ETC, EMC, or ESC). The percentage of thick, moderate, shallow, and no surface crust conditions for each DU are summarized in Figures 2.13 - 2.16, respectively. The highest percentages of thick crust ( $32.9 \%$ and $21.3 \%$, respectively) were found on the eastern side of the GSL in DU5 and DU3 (Fig. 2.13). However, DU5 had a much larger fraction of erodible thick crust than DU3. The smallest percentage of thick crust was observed in DU1 on the south shore of the GSL (Fig. 2.13). The highest percentages of moderate crust ( $22.3 \%$ and $11.3 \%$, respectively) were observed in DU5 and DU9 (Fig. 2.14). More than 50\% of the moderate crust was observed to be erodible in both of these DUs. The smallest percentages of moderate crust were observed in DU1 and DU6. All of the lakebed, with the exception of DU5, had at least 70\% shallow crust coverage (Fig. 2.15). The highest fractions of erodible shallow crusts were observed in DU3 and DU5. The highest percentages of no crust ( $26.4 \%$ and $17.0 \%$, respectively) were observed on the western side of the GSL in DU6 and DU7 (Fig. 2.16). The smallest percentages of no crust were observed in DU3, DU5, and DU9.

Although slightly more than one quarter of the lakebed currently has surface crust conditions conducive to dust production (Fig. 2.12), some of these locations are partially vegetated and some had so little fine material in the soil that no dust plume was generated when the surface was disturbed. Thus, the actual percent of the lakebed which will serve as dust source regions (i.e., "hot spots") will be less than this value.

Figure 2.12 Summary of surface crust characteristics for the entire GSL lakebed.

Figure 2.16 No crust (NC) percentages for each DU.

### 2.4 Testing for Dust Plumes by Manually Disturbing the Surface

One thing that all dust source regions on the lakebed have in common is that they will generate a visible dust plume if the surface is disturbed. A boot test, which involves kicking the surface several times, was completed at each of the 5246 ISM soil sample locations to determine which locations are susceptible to wind erosion. Locations which failed to produce visible dust plumes using this drastic testing method are unlikely to generate dust through wind erosion alone. Locations which did generate dust plumes using this methodology should be considered as potential dust source regions. The 1153 locations which passed the boot test and generated visible dust plumes are shown in Figure 2.17. Detailed maps for each DU are contained in Appendix D. These locations represent $21.9 \%$ of the entire lakebed. It should be noted, however, that some of these locations are partially vegetated or are covered by a non-eroding crust (i.e., TC, MC, or SC). Thus, the actual percent of the lakebed which will serve as dust source regions (i.e., "hot spots") will be less than this value.

### 2.5 Vegetation

The presence of vegetation on the lakebed suppresses dust production by stabilizing the soil and reducing the velocity of the wind near the surface through increased friction. All of the vegetation currently on the lakebed is relatively young (i.e., < 30 years old) because the peak lake level occurred in 1986. The surface crust survey revealed that $15.2 \%$ of the GSL lakebed supports some vegetation. However, the variation among the different DUs was quite large (Fig. 2.18). The maximum vegetative coverage was observed in DU3, DU5, and DU8 along the eastern side of the GSL where the fractions of fine particles (i.e., silt and clay) were highest. Figure 2.19 shows that there is a moderately strong correlation between the amount of vegetative cover and the fraction of fine particles in the soil. The salt content of the soil and the length of time that an area has been exposed are likely additional controlling factors of the vegetation spatial variations. A map summarizing the vegetative coverage of the GSL lakebed is shown in Figure 2.20. Detailed maps of the vegetative coverage in each DU are provided in Appendix E.

Figure 2.17 Map showing the locations which passed the boot test and generated visible dust plumes when disturbed. Detailed maps of each DU are contained in Appendix D.

Figure 2.18 Average total (V) and partial (SV) vegetative cover for each DU.

Figure 2.19 Relationship between the vegetative cover and the fraction of fine particles (i.e., silt and clay) in the soil.

Figure 2.20 Map showing the locations where vegetation was observed on the GSL lakebed. Red markers indicate that the vegetation occurred in an area where the boot test generated dust plumes from the surface. Detailed maps showing the locations of vegetation in each DU are provided in Appendix E.

### 2.6 Dust "Hot Spots"

The most likely regions of the GSL lakebed to act as dust sources are those that have visible fines (VF) (i.e., pass the boot dust plume test), have no vegetation (NV), and have either no crust (NC) or an erodible shallow crust (ESC). This concept is shown in a Venn diagram (Fig. 2.21). There were 4450 NV observations, 1153 VF observations, and 903 NC/ESC observations. The union of these data sets yielded 446 locations which are now identified as dust "hot spots". These "hot spots" represent $8.5 \%$ of the GSL lakebed. The locations of these "hot spots" are shown in Figure 2.22 with detailed "hot spot" maps for each DU included in Appendix F.

Figure 2.21 Venn diagram identifying dust "hot spots" as the union of NV, VF, and NC/ESC.

### 2.7 Key Findings/Uncertainties

## Key Findings

- Dust "hot spots" were identified in all four quadrants of the GSL (i.e., Farmington Bay, Bay River Bay, northwestern Gunnison Bay, and the southern portion of Carrington Bay).
- Dust "hot spots" are rare in most of Gunnison Bay (NW Quadrant) and Gilbert Bay (SW Quadrant).
- Approximately $9 \%$ of the GSL lakebed currently produces dust plumes under appropriate meteorological conditions.
- $22 \%$ of the lakebed generates dust plumes when manually disturbed and could act as dust sources if the protective vegetative cover is reduced or if existing surface crusts are physically destroyed or eroded.
- Approximately $15 \%$ of the lakebed is currently covered by some vegetation.
- Approximately $73 \%$ of the lakebed is protected by shallow, moderate, or thick surface crusts. The remaining $27 \%$ of the lakebed either has no crust or an eroding crust of various thicknesses.
- On average, the GSL lakebed is composed of $95 \%$ sand and $5 \%$ silt and clay. Since it is the silt and clay fractions which are prone to wind erosion, the GSL is less effective at producing dust plumes than many other regional dust sources.
- Access to the two dust source regions on the eastern side of the GSL (i.e., Farmington and Bear River Bays) is severely limited by a combination of private property, vegetative barriers (e.g., phragmites) and fencing. As a result, the fragile surface crusts in these areas are fairly-well protected from disturbance.
- Access to the two dust source regions on the western side of the GSL (i.e., NW Gunnison and Carrington Bays) is not physically restricted by vegetative barriers or fencing. As a result, the fragile surface crusts in these regions are vulnerable to disturbance.
- A total of $757 \mathrm{mi}^{2}$ of exposed lakebed was sampled during this study.

## Uncertainties

$>$ The field work was conducted over a period of 26 months and does not represent a snapshot of the surface crust conditions. As a result, seasonal and shorter time-scale weather variations may have resulted in an underestimate of the number of dust "hot spots" and the fraction of the lakebed capable of generating dust plumes if manually disturbed.
$>$ The GSL elevation varied by more than 3 feet in the southern arm and 5 feet in the northern arm during this study. As a result, some areas which were sampled in late 2016 are now under water and some areas which were exposed in late 2016 were covered by water before they could be sampled.
$>$ The number of dust "hot spots" does not necessarily correlate with the amount of dust produced in a given area due to a variety of other contributing factors (e.g., soil particle size distribution, soil moisture, surface crust type, etc.). Further research is required to determine which of the four primary GSL dust source regions generates the highest concentrations of airborne particulate matter.

Figure 2.22 Map showing the locations of the Great Salt Lake dust "hot spots" (i.e., no vegetation, no crust or an erodible shallow crust). Detailed "hot spot" maps for each DU are provided in Appendix F.

## 3. How Common are Strong Wind Events?

### 3.1 Available Data

To investigate the strong wind events capable of generating local dust plumes, data from several weather stations and Utah Division of Air Quality (UDAQ) monitoring sites were analyzed over a 10-year period (i.e., 2006-2015). The four main sites include the Salt Lake City International Airport (KSLC, from the Automated Surface Observing System, ASOS) and the UDAQ monitoring stations at Hawthorne Elementary (Salt Lake City, HW), Bountiful (BV), and Lindon (LN)). These data are all available at 1-min resolution. Auxiliary datasets in the vicinity of the new Utah State Correctional Facility include two stations operated near the Kennecott Utah Copper tailings ponds, named Dike (KCCO5) and Center Tailings (KCC13), and an additional UDAQ monitoring station, Saltair (QSA). For these additional sites, hourly data was retrieved from mesowest (http://mesowest.utah.edu/, Horel et al. 2002). See Table 3.1 for station details and Fig. 3.1 for a map of the wind observation locations.

Figure 3.1. Map showing locations of wind observations. A: Salt Lake City International Airport (KSLC), B: Hawthorne Elementary (HW), C: Bountiful (BV), D: Lindon (LN), E: Kennecott Dike (KCCO5), F: Kennecott Center Tailings (KCC13), G: Saltair (QSA). The location of the new Utah State Correction Facility is shown as a red square. [Source: mapper.acme.com.]

Table 3.1 Meteorological Measurement Locations, Time Intervals, and Data Coverage.

| Site | Latitude <br> Longitude <br> Elevation | Data <br> interval | Data <br> Coverage | Measurement Height <br> (above ground level) |

### 3.2 Previous Research

Although particles smaller than $\sim 75$ micrometers in diameter are susceptible to lofting by winds (Nickling, 1988), considerable uncertainty exists regarding the 'threshold' wind speed needed for various surface and soil types for the onset of saltation and resulting wind erosion and dust emission. The Western Regional Air Partnership made an assumption of a $20 \mathrm{mph}\left(9 \mathrm{~m} \mathrm{~s}^{-1}\right)$ threshold wind velocity for dust lofting (Countess Environmental, 2006). Pelletier (2006) modeled dust transport under a range of soil moistures for the soda (dry) lake playa in California, and found that the threshold wind velocity for onset of saltation ranged between 8 and $14 \mathrm{~m} \mathrm{~s}^{-1}$. Steenburgh et al. (2012) found that the mean sustained hourly mean wind speed
during dust reports at the Salt Lake City airport was $11.6 \mathrm{~m} \mathrm{~s}^{-1}$. Because of the uncertainty in the threshold wind velocity for the GSL, we perform the following meteorological analyses for both the best estimate ( $11 \mathrm{~m} \mathrm{~s}^{-1}$ ) and more conservative ( $9 \mathrm{~m} \mathrm{~s}^{-1}$ ) threshold wind velocities.

Two previous studies have looked at the climatology of dust episodes in the Salt Lake City area (Steenburgh et al., 2012 and Hahnenberger and Nicoll, 2012). The focus of these studies was the long-distance transport of dust from Nevada and southern Utah into the Great Salt Lake basin. Because of this, we would expect their findings on dust storm frequency to impact all portions of the Wasatch Front relatively similarly. These studies did not take into account the recent and historic periods when the Great Salt Lake playa surfaces were exposed as potential dust sources due to water diversions and drought. The key findings of the Steenburgh et al. (2012) and Hahnenberger and Nicoll (2012) studies are:

- The frequency distribution of wind directions during dust events is bimodal (southerly or northerly).
- Southerly wind episodes are more likely to be associated with dust than northerly wind episodes (note, however, the climatology was conducted mostly during higher GSL level years when no dust source would have been available on the GSL playa).
- Widespread (i.e., regional) dust episodes over northern Utah occur 4-5 times per year on average, and are most common in the spring.
- High winds and dust reports are most common between noon and 6 pm local time.
- Most dust reports happen within 2 hours of a cold frontal passage.
- Most dust episodes (66\%) are associated with synoptic weather patterns (e.g., trough or ahead of or during a cold frontal passage), while a lesser portion of episodes are associated with thunderstorms and convection (33\%).

### 3.3 Climatology of Strong Wind Events Along the Wasatch Front

3.3.1 Wind Rose Analysis

A windrose analysis was performed for both general conditions (excluding calm winds $<1 \mathrm{~m} \mathrm{~s}^{-1}$ ) and for high wind conditions with wind speeds $>11 \mathrm{~m} \mathrm{~s}^{-1}$. Windroses for general conditions at all sites are shown in Figure 3.2 (main sites) and Figure 3.3 (auxiliary sites). For the analysis of the main sites (KSLC, HW, BV), the data was homogenized. This means that only data is included from times when all four locations were reporting. This avoids potential biases due to equipment outages. Data coverage for the homogenized dataset is $67.21 \%$. The analysis of the three auxiliary sites (KCC05, KCC13, QSA) includes all available data.

Figure 3.2 Windrose plots for KSLC, HW, BV and LN. Only data is included when all stations were reporting. Winds below $1 \mathrm{~m} \mathrm{~s}^{-1}$ are excluded from wind statistics. Value n gives the number of 1-minute data points where winds exceed $1 \mathrm{~m} \mathrm{~s}^{-1}$.

Figure 3.3 Windrose plots for KCC13, KCCO5 and QSA. All available data is included. Value n gives the number of hourly data points where winds exceed $1 \mathrm{~m} \mathrm{~s}^{-1}$.

The wind field at the study locations reflects the orientation of the key geographic features of the Salt Lake City basin. The main wind directions at the Salt Lake City International Airport (KSLC) are S-SE and NNW-N (Fig. 3.2). Wind speeds are generally higher at KSLC than at the other three main sites. The main wind directions at Hawthorne (HW) and Bountiful (BV) are WNW-NNW and E-S (Fig. 3.2) with the strongest wind speeds from the SSE-SSW and NW-NNW directions. The wind field in Lindon (LN) is dominated by generally weak E to ESE flow or flows from the northwesterly quadrant.

Windrose plots for high wind conditions (i.e., $\geq 11 \mathrm{~m} \mathrm{~s}^{-1}$ ) are shown in Figures 3.4 and 3.5 for the four main sites and the three auxiliary locations. High wind conditions are defined here as times when the wind speed exceeds a threshold value of $11 \mathrm{~m} \mathrm{~s}^{-1}$. Under these conditions, the lofting of particulate matter is likely to occur, and particulates are suspended into the flow field (Steenburgh et al., 2012; Pelletier, 2006). The strong winds are generally associated with either southerly or northwesterly flows. In addition, the weak signature of strong easterly downslope winds ("Wasatch Winds") can be seen in the windroses for Bountiful and to some extent, Hawthorne.

### 3.3.2 Strong Wind Conditions

High wind conditions are more likely to occur at KSLC than in the urbanized areas around HW, BV and LN. The 10-year record at KSLC contains 443 days when winds were $>11 \mathrm{~m} \mathrm{~s}^{-1}$ for more than 15 minutes, corresponding to $13 \%$ of all days when data was reported. In contrast, only 12 $(27,41)$ days meet these criteria at HW (LN, BV) (Table 3.2). When lowering the wind speed threshold to $9 \mathrm{~m} \mathrm{~s}^{-1}$, a conservative reference value used for threshold velocities in some other studies, the frequency of days experiencing such winds for at least 15 minutes, rises to $26 \%$ at KSLC and $3-4 \%$ at HW, LN and BV. This clearly illustrates that high winds are much more likely to occur near the new Utah State Correction Facility site than at the current UDAQ monitoring stations.

The auxiliary sites on the Kennecott Utah Copper tailings operations report only hourly and have a reduced period of record (Table 3.2). The high frequency of above-threshold winds (Table 3.2) is most likely due to the exposure of the sites to the flow field on the elevated terrain of the high tailing piles ( 65 m and 50 m above the height of KSLC). Under high wind conditions, the flow is most frequently from a southerly direction. Southerly wind directions constitute $78 \%$ of the high-wind observations at KSLC, $71 \%$ at HW, $91 \%$ at LN, and $81 \%$ at BV (Table 3.2).

Figure 3.4 Windrose plots of high wind conditions for KSLC, HW, BV and LN. Data is included only when all stations were reporting. Winds $<11 \mathrm{~m} \mathrm{~s}^{-1}$ are excluded from the wind statistics. The n value gives the number of 1-minute data points when winds exceed $11 \mathrm{~m} \mathrm{~s}^{-1}$.

Figure 3.5 Windrose plots of high wind conditions for KCC13, KCCO5 and QSA. All available data is included. The n value gives the number of hourly data points when winds exceed $11 \mathrm{~m} \mathrm{~s}^{-1}$.

Table 3.2 Summary of high-wind conditions at the selected study locations, illustrating the higher frequency of strong ( $\geq 11 \mathrm{~m} \mathrm{~s}^{-1} ; \geq 9 \mathrm{~m} \mathrm{~s}^{-1}$ ) winds near the new Utah State Correction Facility site, and the dominating southerly winds direction during high-wind events.

| Site | High wind $\geq 11 \mathrm{~m} \mathrm{~s}^{-1}$ occurrence based on all available data | \# days in record with $\geq 11 \mathrm{~m} \mathrm{~s}^{-1}$ wind readings for more than 15 min | \% of $\geq 11 \mathrm{~m} \mathrm{~s}^{-1}$ winds with a southerly wind component | \% of $\geq 11 \mathrm{~m} \mathrm{~s}^{-1}$ winds with a northerly wind component |

* Statistics for $\geq 9 \mathrm{~m} \mathrm{~s}^{-1}$ in parentheses.

### 3.3.3 Meteorological Drivers of Observed Wind Regimes

Several weather patterns are associated with high wind events and are directly related to the wind direction of the strong winds. These weather patterns are:

- prefrontal southerly flow,
- postfrontal northwesterly flow,
- easterly downslope windstorms ("Wasatch Winds"), and
- outflows from thunderstorms.

Southerly wind directions are the most common, as shown in the wind climatology (Figs. 3.4 \& 3.5 and Table 3.2). These strong southerly winds are driven primarily by approaching weather systems, and they typically persist for several hours but can blow for several days. Strong northwesterly winds are observed most frequently along and behind a cold front and typically persist for 1-4 hours. The Wasatch winds are strong easterly downslope windstorms that are confined to west-facing slopes and foothills. Signatures of these events are only seen at Bountiful, and to a lesser extent, at Hawthorne. Thunderstorm outflows occur during convective weather patterns and can cause strong winds from either a southerly or northwesterly direction during the April-October period.

### 3.4 Key Findings/Uncertainties

## Key findings of the general wind climatology

- The Wasatch and Oquirrh mountains and the Great Salt Lake and other geographic features impact the wind speed and wind direction across the region.
- South-southeast and north-northwest wind directions are the most commonly observed wind directions at all locations.
- Wind speeds are higher at the sites located at and west of the Salt Lake City International Airport (KSLC, KCC05, KCC13, QSA) than at the urban sites on the eastern slope of the Wasatch Mountains (HW, BV, LN).
- The highest wind speeds ( $\geq 15 \mathrm{~m} \mathrm{~s}^{-1}$ ) near the new Utah State Correction Facility site (KSLC, KCC13, KCC05, and QSA) occur most frequently during south-southeasterly wind episodes.

## Key findings - high wind conditions

- High winds ( $\geq 11 \mathrm{~m} \mathrm{~s}^{-1}$ ) occur at $1.1 \%$ of the time at KSLC.
- High winds ( $\geq 11 \mathrm{~m} \mathrm{~s}^{-1}$, for more than 15 min ) occurred on roughly 44 days every year at KSLC, but only about once every year at Hawthorne (HW)
- High wind conditions are more likely to occur near the new Utah State Correctional Facility site than at other locations in the basin. This is confirmed by the data from the Kennecott tailing sites.
- Near the new Utah State Correctional Facility site, high winds are predominantly southerly ( 62 to $78 \%$ of the time). They are otherwise from northwesterly directions.

## Uncertainties

> Drastic declines in the GSL lake level result in a climatology for this study that is biased for a larger GSL surface area. The impact of the lower lake level on the wind speed and direction climatology and dust exposure, is unknown.
> We did not attempt to separate "dry" soil periods (when dust could be blown by the wind) from "wet" soil periods when winds would not loft dust, as there is insufficient soil moisture data to make such estimates.
> This study used several different instrument systems for wind measurements collected by the UDAQ, National Weather Service, and Kennecott Utah Copper. While the data passes gross quality control checks and appears of high quality, some uncertainty on the exact measurement height of the anemometers and the calibration of the instruments remains.
> Determining the actual threshold wind velocity necessary to generate dust plumes from the GSL is a complex function of the soil particle size distribution, surface crust characteristics, and soil moisture and was beyond the scope of this project. Thus, future research will need to be undertaken to determine the threshold wind velocities for the known GSL dust "hot spots".

## 4. Do Dust Plumes from the GSL Contain Harmful Heavy Metals?

### 4.1 Methodology

As described in Section 2.1, the soil samples from each SU were composited into a total of 122 samples. These soil samples were then dried in an oven at $105^{\circ} \mathrm{C}$ for a period of 24 hours, disaggregated, and sieved. The smallest sieve (\#200) size yielded particles with diameters < 74 $\mu \mathrm{m}$ comprising silt and clay. These fine particles were then placed into a resuspension chamber where they were aerosolized using compressed air. The airborne soil particles were pulled through a URG Corporation $\mathrm{PM}_{10}$ inlet at a flow rate of 16.7 lpm to separate out the respirable, $\mathrm{PM}_{10}$, particles. The $\mathrm{PM}_{10}$ particles were subsequently collected using two different methodologies. The first methodology was optimized for chemical analysis by InductivelyCoupled Plasma Mass Spectrometry (ICPMS) while the second methodology was optimized for chemical analysis by Synchrotron X-Ray Fluorescence (SXRF).

ICPMS requires a sample mass of > 10 mg to provide measurements which are reliably above the minimum detection limits. To collect the requisite $\mathrm{PM}_{10}$ mass, 30 to 90 g of the silt and clay particles ( $\# 200$ sieve) were placed in a weigh boat and aerosolized inside a $0.5 \mathrm{~m}^{3}$ resuspension chamber using compressed air. The $\mathrm{PM}_{10}$ particles which passed through the URG inlet were then collected onto pre-weighed, 25 mm , Teflon filters for a period of 15 minutes. The loaded Teflon filters were then reweighed to ensure that they met the 10 mg minimum mass requirement. Prior to the ICPMS analysis, the samples were completely digested in hydrofluoric acid. The sample preparation and ICPMS analysis were performed in the Metals Lab at the University of Utah (Department of Geology \& Geophysics). The ICPMS system utilized an Agilent 7500ce, quadrupole mass-spectrometer with an octopole reaction system to preferentially remove polyatomic interferences. Calibration of the system was performed using a variety of NIST-traceable standards (Table 4.1).

SXRF requires much less sample mass than ICPMS. As a result, we were able to use an 8 -stage rotating DRUM impactor to measure the size-resolved elemental composition of the resuspended $\mathrm{PM}_{10}$ soil. We placed 0.3 g of the silt and clay particles (\#200 sieve) into a weigh boat and aerosolized it inside the resuspension chamber using compressed air. The $\mathrm{PM}_{10}$ particles which passed through the URG inlet at a flow rate of 16.7 lpm were then sampled by an 8 -stage rotating DRUM impactor for a period of 15 minutes. The DRUM sampler impacted the particles onto a series of greased Mylar substrates. The DRUM separated the particles into the following size ranges based on their aerodynamic diameters: $10-5 \mu \mathrm{~m}, 5-2.5 \mu \mathrm{~m}, 2.5-$ $1.1 \mu \mathrm{~m}, 1.1-0.75 \mu \mathrm{~m}, 0.75-0.56 \mu \mathrm{~m}, 0.56-0.34 \mu \mathrm{~m}, 0.34-0.24 \mu \mathrm{~m}$, and $0.24-0.09 \mu \mathrm{~m}$. The Mylar substrates were coated with a $1 \%$ Apiezon Type-L grease dissolved in toluene. The purpose of the grease was to minimize incorrect particle sizing due to particle bounce. The DRUM substrates were shipped to the Advanced Light Source at Lawrence Berkeley National Lab where we analyzed them using SXRF. Deconvolution of the raw X-ray spectra was performed using the Quantitative X-ray Analysis System (QXAS) X-ray peak-fitting software package which was developed by the IAEA Laboratories in Seibersdorf, Austria. Quantitative analysis was performed by calibrating the response of the system to a comprehensive set of 40
single- and multi-element NIST-traceable standards (Table 4.1). The SXRF analysis is completely non-destructive and did not require any additional sample preparation.

The SXRF analysis produces elemental areal density measurements in units of $\mathrm{ng} \mathrm{cm}^{-2}$ while the ICPMS analysis produces elemental mass fractions in units of $\mathrm{mg} / \mathrm{kg}$ (i.e., parts per million). To merge the two data sets it was necessary to normalize the SXRF data using Fe (i.e., iron). Iron was used to normalize the SXRF data set because it is the most abundant soil element measured by both techniques. It is also the element for which SXRF has the greatest sensitivity. To verify that the normalization procedure worked as expected, data from the two analytical techniques were compared for overlapping elements. The results for the major soil elements not associated with evaporite minerals (i.e., Al, Mn , and Ti ) and one of the most abundant contaminants $(\mathrm{Cu})$ are shown in Figure 4.1. The entire $\mathrm{PM}_{10}$ elemental mass fraction dataset is included as Appendix G.

## Table 4.1 Summary of Analytical Techniques Used for this Study.

| Atomic \# Element | Technique(s) | Uncertainty (\%) | Atomic \# Element | Technique(s) | Uncertainty (\%) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 3-Li | ICPMS | $\pm 25 \%$ | $38-\mathrm{Sr}$ | ICPMS/SXRF | $\pm 25 \% / \pm 25 \%$ |
| $4-\mathrm{Be}$ | ICPMS | $\pm 10 \%$ | $39-Y$ | ICPMS | $\pm 25 \%$ |
| 5-B | ICPMS | $\pm 25 \%$ | $40-\mathrm{Zr}$ | SXRF | $\pm 25 \% / \pm 25 \%$ |
| $11-\mathrm{Na}$ | ICPMS | $\pm 10 \%$ | 42 - Mo | ICPMS | $\pm 10 \%$ |
| $12-\mathrm{Mg}$ | ICPMS/SXRF | $\pm 10 \% / \pm 25 \%$ | $47-\mathrm{Ag}$ | ICPMS | $\pm 10 \%$ |
| 13 - Al | ICPMS/SXRF | $\pm 10 \% / \pm 20 \%$ | $48-\mathrm{Cd}$ | ICPMS | $\pm 10 \%$ |
| $14-\mathrm{Si}$ | SXRF | $\pm 15 \%$ | $51-\mathrm{Sb}$ | ICPMS | $\pm 10 \%$ |
| 15-P | SXRF | $\pm 15 \%$ | $55-\mathrm{Cs}$ | ICPMS | $\pm 25 \%$ |
| 16-S | SXRF | $\pm 15 \%$ | $56-\mathrm{Ba}$ | ICPMS | $\pm 10 \%$ |
| $17-\mathrm{Cl}$ | SXRF | $\pm 15 \%$ | 57 - La | ICPMS | $\pm 25 \%$ |
| 19-K | ICPMS/SXRF | $\pm 10 \% / \pm 15 \%$ | $58-\mathrm{Ce}$ | ICPMS | $\pm 25 \%$ |
| 20-Ca | ICPMS/SXRF | $\pm 10 \% / \pm 15 \%$ | $59-\mathrm{Pr}$ | ICPMS | $\pm 25 \%$ |
| $21-\mathrm{Sc}$ | ICPMS | $\pm 25 \%$ | $60-\mathrm{Nd}$ | ICPMS | $\pm 25 \%$ |
| 22- Ti | ICPMS/SXRF | $\pm 25 \% / \pm 15 \%$ | 62-Sm | ICPMS | $\pm 25 \%$ |
| $23-\mathrm{V}$ | ICPMS/SXRF | $\pm 10 \% / \pm 15 \%$ | 63 - Eu | ICPMS | $\pm 25 \%$ |
| $24-\mathrm{Cr}$ | ICPMS/SXRF | $\pm 10 \% / \pm 15 \%$ | 64-Gd | ICPMS | $\pm 25 \%$ |
| $25-\mathrm{Mn}$ | ICPMS/SXRF | $\pm 10 \% / \pm 15 \%$ | $65-\mathrm{Tb}$ | ICPMS | $\pm 25 \%$ |
| $26-\mathrm{Fe}$ | ICPMS/SXRF | $\pm 10 \% / \pm 15 \%$ | 66 - Dy | ICPMS | $\pm 25 \%$ |
| 27 - Co | ICPMS/SXRF | $\pm 10 \% / \pm 15 \%$ | 67 - Ho | ICPMS | $\pm 25 \%$ |
| $28-\mathrm{Ni}$ | ICPMS/SXRF | $\pm 10 \% / \pm 15 \%$ | 68 - Er | ICPMS | $\pm 25 \%$ |
| $29-\mathrm{Cu}$ | ICPMS/SXRF | $\pm 10 \% / \pm 15 \%$ | $70-\mathrm{Yb}$ | ICPMS | $\pm 25 \%$ |
| $30-\mathrm{Zn}$ | ICPMS/SXRF | $\pm 10 \% / \pm 15 \%$ | 71 - Lu | ICPMS | $\pm 25 \%$ |
| $31-\mathrm{Ga}$ | SXRF | $\pm 15 \%$ | 81-TI | ICPMS | $\pm 10 \%$ |
| 33-As | ICPMS/SXRF | $\pm 10 \% / \pm 15 \%$ | $82-\mathrm{Pb}$ | ICPMS/SXRF | $\pm 10 \% / \pm 15 \%$ |
| $34-\mathrm{Se}$ | ICPMS/SXRF | $\pm 10 \% / \pm 15 \%$ | $90-\mathrm{Th}$ | ICPMS | $\pm 25 \%$ |
| $35-\mathrm{Br}$ | SXRF | $\pm 15 \%$ | 92-U | ICPMS | $\pm 10 \%$ |
| $37-\mathrm{Rb}$ | ICPMS/SXRF | $\pm 25 \% / \pm 25 \%$ |  |  |  |

[Note: Bold indicates which analytic technique was chosen when both ICPMS and SXRF were available]

Figure 4.1 Bivariate correlation plots of the ICPMS and normalized SXRF data for the major soil elements not associated with evaporites (i.e., $\mathrm{Al}, \mathrm{Mn}$, and Ti ) and one of the most abundant contaminants (Cu). The regression statistics for each bivariate correlation are shown in the upper left corner of the plots.

### 4.2 EPA Regional Screening Levels

The Environmental Protection Agency (EPA) is authorized by the Clean Air Act to establish air quality standards designed to protect human and ecological health. The actual risk to a given receptor depends upon the concentration of the contaminant, the exposure, and its inherent toxicity. Both the concentration and toxicity of a contaminant are relatively straightforward to measure. Exposure, on the other hand, is extremely difficult to quantify because it depends upon where the receptor is located, whether it moves, how much time is spent indoors versus outdoors, and the respiration rate. As a result, exposure assessments are typically time consuming and expensive and are only performed when necessary. To determine whether a site-specific exposure assessment is necessary, the EPA has established Regional Screening Levels (RSLs) for a large number of contaminants. The RSLs use conservative estimates for exposure to identify the ambient concentrations which would result in a target cancer risk of 1 in 1 million. Multiple RSLs exist for a given site depending on the degree of exposure (i.e., resident or industrial) and the exposure pathway (i.e., ingestion or inhalation). RSLs have been established for 808,343 , and 798 contaminants for soil, air, and tapwater, respectively. This
study will determine whether any of the species measured in the soil samples from the GSL playa exceed the RSLs established for residential or industrial exposures. Species which do not exceed the RSLs established by the EPA should not pose a health risk to the adjacent populations. Species with concentrations greater than the RSLs established by the EPA have the potential to adversely impact human health and should undergo a site-specific exposure assessment to determine the actual risk levels. The data presented in this section could also be used to assess ecological health risks. However, such an assessment is beyond the scope of this project.

## 4.3 $\quad \mathrm{PM}_{10}$ Elemental Mass Fractions

Substantial effort was expended to dry, disaggregate, sieve, resuspend, and then collect the PM 10 component of the GSL soil samples for subsequent elemental analysis. This effort was warranted because it is the $\mathrm{PM}_{10}$ particles which are considered to be respirable. Particles larger than $10 \mu \mathrm{~m}$ do no remain in the atmosphere for very long and are effectively removed from the airstream prior to entering the lungs. The ICPMS and SXRF analytical techniques were able to quantify a total of 53 elements in the resuspended soil samples (Table 4.1). 28 of these elements do not have health standards (i.e., RSLs). Data for these elements are included in section 4.3.1 for completeness and could be useful in the future if RSLs are established at a later date. Elements with mass fractions below both the Residential and Industrial RSLs are summarized in section 4.3.2. Elements with some values exceeding the Residential RSLs are summarized in section 4.3.3. Elements with some values exceeding the Industrial RSLs are summarized in section 4.3.4.

Most soils have a composition which closely matches the average abundance of elements in the Earth's crust (Table 4.2). However, the soil from the GSL lakebed is highly enriched in elements associated with evaporite minerals (e.g., $\mathrm{Ca}, \mathrm{Mg}, \mathrm{S}, \mathrm{Sr}, \mathrm{Cl}, \mathrm{Li}$, and B ). Enrichment factors, which are defined as the measured mass fraction divided by the crustal mass fraction, are shown in Table 4.2 as well.

Typically, evaporite deposits occur in closed marine basins where evaporation exceeds inflow. The deposits often show a repeated sequence of minerals, indicating cyclic conditions with a mineralogy determined by solubility. The most important minerals and the sequence in which they form include calcite $\left(\mathrm{CaCO}_{3}\right)$, gypsum $\left(\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}\right)$, anhydrite $\left(\mathrm{CaSO}_{4}\right)$, halite ( NaCl ), polyhalite $\left(\mathrm{K}_{2} \mathrm{Ca}_{2} \mathrm{Mg}\left(\mathrm{SO}_{4}\right)_{4} \cdot 2 \mathrm{H} 2 \mathrm{O}\right)$, and lastly potassium and magnesium salts (e.g., KCl and $\mathrm{MgCl}_{2}$ ). These sequences have been reproduced in laboratory experiments and, therefore, the physical and chemical conditions for evaporite formation are well known. In contrast to basin deposits, extensive thin-shelf deposits are known and are thought to be the result of shallow, ephemeral seas. Non-marine evaporites formed by streams flowing into closed depressions, especially in arid regions, give rise to deposits of borates, nitrates, and sodium carbonates. Such deposits occur in Utah and southern California in the United States. (Encyclopedia Britannica, 2018)

Table 4.2 Comparison of the GSL PM 10 Soil to the Average Abundance of Elements in the Earth's Crust (Taylor and McLennan, 1985).

| Element | Avg Crustal Abundance (mg/kg) | Avg. GSL PM ${ }_{10}$ Soil Abundance ( $\mathrm{mg} / \mathrm{kg}$ ) | Enrichment Factor | Element | Avg Crustal Abundance ( $\mathrm{mg} / \mathrm{kg}$ ) | Avg. GSL PM ${ }_{10}$ Soil Abundance ( $\mathrm{mg} / \mathrm{kg}$ ) | Enrichment Factor |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Strontium carbonate $\left(\mathrm{SrCO}_{3}\right)$ typically coprecipitates with gypsum (Gogda et al., 2017) while lithium and boron are commonly found in concentrated brine solutions associated with terminal basin lakes (Peiro et al., 2013). The fact that neither sodium nor potassium have enrichment factors $>1$ should not be interpreted as the absence of significant quantities of NaCl or KCl . Rather, the lower enrichment factors result from the fact that much of the normal soil has been displaced by evaporites. This contention is supported by the low enrichment factors for $\mathrm{Si}, \mathrm{Al}, \mathrm{Fe}$, and Ti , which are all < 0.5.

The enrichment factor analysis also reveals that several heavy metals are significantly enhanced in the $\mathrm{PM}_{10}$ soil from the GSL relative to the average crustal abundance. The enrichment factors for $\mathrm{As}, \mathrm{Sb}, \mathrm{Ag}, \mathrm{Cu}$, and U were $24.7,11,4.4,2.6$, and 2.1 , respectively. Although some of these values are quite high, they do not necessarily indicate the presence of industrial or municipal pollution. It is possible that the enhancements merely reflect regional geologic composition traits which differ from the globally-averaged values. Further analysis will be presented in Section 6 to determine whether these enhancements are due to natural or anthropogenic processes.

A summary of all the $\mathrm{PM}_{10}$ soil elemental mass fraction data is shown in Figure 4.2. The median for each element is identified by a round circle while the interquartile ranges (i.e., between the $25^{\text {th }}$ and $75^{\text {th }}$ percentiles) are indicated by the solid blue boxes. The solid lines indicate $\pm 2.7 \sigma$ (i.e., standard deviation). For a normally-distributed dataset, $\pm 2.7 \sigma$ would encompass $99.3 \%$ of the data. Outliers are shown as small red dots. The entire $\mathrm{PM}_{10}$ mass fraction data set for all DUs and SUs is included as Appendix G.

Figure 4.2 Elemental mass fractions for all of the $\mathrm{PM}_{10}$ soil samples collected from the exposed lakebed of the GSL. The median for each element is identified by a round circle while the interquartile ranges (i.e., between the $25^{\text {th }}$ and $75^{\text {th }}$ percentiles) are indicated by the solid blue boxes. The solid lines indicate $\pm 2.7 \sigma$ (i.e., standard deviation). For a normally-distributed dataset, $\pm 2.7 \sigma$ would encompass $99.3 \%$ of the data. Outliers are shown as small red dots.
4.3.1 Elements Without Health Standards

None of the elements shown in Figures 4.3 through 4.7 are in the EPA RSL database indicating that no known health hazards currently exist.

Figure 4.3 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions ( $\mathrm{mg} / \mathrm{kg}$ ) for $\mathrm{Br}, \mathrm{Ca}, \mathrm{Ce}, \mathrm{Cs}, \mathrm{Cl}$ and Dy.

Figure 4.7 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions ( $\mathrm{mg} / \mathrm{kg}$ ) for $\mathrm{Th}, \mathrm{Ti}, \mathrm{Yb}$, and Y .

### 4.3.2 Elements Below Health Standards

None of the elements shown in Figures 4.8 through 4.10 exceed the EPA Composite Residential or Industrial RSLs for a target cancer risk (TR) of 1 in 1 million and a target hazard quotient (THQ) of 0.1.

Figure 4.8 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions (mg/kg) for $\mathrm{Al}, \mathrm{Ba}, \mathrm{Be}, \mathrm{B}, \mathrm{Cd}$, and Cr .

Figure 4.10 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions ( $\mathrm{mg} / \mathrm{kg}$ ) for $\mathrm{Ag}, \mathrm{Sr}, \mathrm{U}$, and Zn .
4.3.3 Elements Exceeding Residential RSLs

All of the elements shown in Figure 4.11 have some values which exceed the EPA Composite Residential, but not the Industrial, RSLs for a target cancer risk (TR) of 1 in 1 million and a target hazard quotient (THQ) of 0.1.

Figure 4.11 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions ( $\mathrm{mg} / \mathrm{kg}$ ) for $\mathrm{Sb}, \mathrm{Co}, \mathrm{Cu}, \mathrm{Mn}$, and V.

### 4.3.4 Elements Exceeding Industrial RSLs

All of the elements shown in Figure 4.12 have some values which exceed the EPA Composite Residential and Industrial RSLs for a target cancer risk (TR) of 1 in 1 million and a target hazard quotient (THQ) of 0.1. In the case of As, all of the observed values were greater than the Industrial RSL.

Figure 4.12 Histograms of $\mathrm{PM}_{10}$ soil elemental mass fractions (mg/kg) for $\mathrm{As}, \mathrm{La}, \mathrm{Li}$, and Zr .

### 4.4 Key Findings/Uncertainties

## Key findings

- The $\mathrm{PM}_{10}$ soil from the GSL lakebed is highly enriched in elements associated with evaporite minerals (e.g., $\mathrm{Ca}, \mathrm{Mg}, \mathrm{S}, \mathrm{Sr}, \mathrm{Cl}, \mathrm{Li}$, and B ).
- 28 of the 53 elements measured do not currently have health standards and, as such, pose no known health risks. These elements include: $\mathrm{Br}, \mathrm{Ca}, \mathrm{Ce}, \mathrm{Cl}, \mathrm{Cs}, \mathrm{Dy}, \mathrm{Er}, \mathrm{Eu}, \mathrm{Ga}, \mathrm{Gd}$, Ho, K, Lu, Mg, Na, Nd, P, Pr, Rb, S, Sc, Sm, Tb, Th, Ti, Tl, Y, and Yb.
- 16 of the elements measured were below both the Residential and Industrial RSLs established by the EPA and, therefore, pose no health risks to adjacent populations. These elements include: $\mathrm{Ag}, \mathrm{Al}, \mathrm{B}, \mathrm{Ba}, \mathrm{Be}, \mathrm{Cd}, \mathrm{Cr}, \mathrm{Fe}, \mathrm{Mo}, \mathrm{Ni}, \mathrm{Pb}, \mathrm{Se}, \mathrm{Si}, \mathrm{Sr}, \mathrm{U}$, and Zn .
- 5 of the elements measured had some values which exceeded the Residential, but not the Industrial, RSLs established by the EPA. These elements include: $\mathrm{Co}, \mathrm{Cu}, \mathrm{Mn}, \mathrm{Sb}$, and V .
- 4 of the elements measured had some values which exceeded both the Residential and Industrial RSLs established by the EPA. These elements include: As, La, Li, and Zr.
- Site-specific exposure assessments should be performed for $\mathrm{As}, \mathrm{Co}, \mathrm{Cu}, \mathrm{La}, \mathrm{Li}, \mathrm{Mn}, \mathrm{Sb}, \mathrm{V}$, and Zr to determine whether the measured concentrations of these elements pose health risks at the observed exposure frequencies.

## Uncertainties

> The valence state of Cr has a huge impact on its toxicity with $\mathrm{Cr}(\mathrm{VI})$ being much more toxic than Cr (III). The comparison of Cr to the RSLs assumed that all of the Cr was in the form of Cr (III). Follow-up work should be conducted to verify this assumption.
> Although 9 elements exceeded the Residential RSLs established by the EPA, it does not necessarily mean that these elements pose a health risk to adjacent populations because the exposure frequency used in the RSL calculation is extremely conservative. To determine the actual health risk, a site-specific exposure assessment for these elements should be performed.
$>$ The $\mathrm{PM}_{10}$ elemental data presented in this report represent the composition of the top 1 cm of the exposed lakebed. Deeper samples (i.e., $1-4 \mathrm{~cm}$ ) were collected as part of this study but not analyzed. Thus, the composition of the $\mathrm{PM}_{10}$ soil in dust plumes originating from the exposed lakebed could change if the top 1 cm is deflated (i.e. removed from the surface) through the process of wind erosion.
$>$ This study did not investigate the impact of GSL dust plumes on the local $\mathrm{PM}_{10}$ or $\mathrm{PM}_{2.5}$ concentrations. If the GSL generates $\mathrm{PM}_{10}$ or $\mathrm{PM}_{2.5}$ concentrations greater than the threshold values established by the EPA for criteria pollutants, then the dust could pose a health hazard even if none of the constituent components (i.e., heavy metals) are deemed hazardous during a site-specific exposure assessment.
> This study did not investigate potential biological hazards contained in the dust from the GSL.

## 5. How Will Lake Elevation Fluctuations Impact Dust Production?

### 5.1 Methodology

During the Fall of 2016, the Automated Geographic Reference Center (AGRC), Utah Geological Survey, and the Utah Division of Forestry, Fire and State Lands acquired detailed elevation data for almost the entire exposed lakebed of the GSL (Fig. 5.1). The data were acquired by installing a LiDAR system onto an aircraft and flying a gridded pattern over the exposed lakebed. The LiDAR system sent out a pulsed laser light beam toward the ground and measured the time required for the laser light beam to reflect off the surface and return to the aircraft. The return time was then used in conjunction with aircraft altitude and position data to determine the elevation of underlying surface with a high degree of accuracy. The root-mean-square error (RMSE) of the resultant dataset was determined to be $\leq 10 \mathrm{~cm}$. This study used the bare-earth digital elevation model (DEM). The GPS coordinates of each surface crust sample identified as having visible fines were combined with the bare-earth DEM in the Global Mapper (v19.1.0) software package to determine the elevation of each potential dust source "hot spot".

The calibration of the bare-earth DEM was tested by 1) comparing the GSL elevation derived from the LiDAR data with the USGS direct measurements of the lake elevation, and 2) comparing the LiDAR data to the bathymetry data set of the lakebed obtained in 2005 and 2006 by the US Geological Survey (USGS). The overlap between the bathymetry data and the LiDAR data is limited to elevations between 4194 ft and 4200 ft .

The LiDAR data was acquired during 48 flights which occurred on 26 days between 09/03/2016 and $11 / 30 / 2016$. The lake elevation statistics for the days on which flights occurred are shown in Table 5.1. The average difference between the USGS and LiDAR data is approximately 3.5 ft with the LiDAR data being higher. We do not know the reason for this discrepancy, but will adjust all of the LiDAR data down by 3.5 ft so that it matches the USGS lake elevation data.

Table 5.1 Comparison of USGS GSL Elevation Data with LiDAR Data.

|  | Average <br> GSL Elevation <br> $(\mathrm{ft})$ | Maximum <br> GSL Elevation <br> $(\mathrm{ft})$ | Minimum GSL <br> Elevation (ft) | Standard <br> Deviation GSL <br> Elevation (ft) |
| :---: | :---: | :---: | :---: | :---: |
| Saltair Boat Harbor <br> (Southern GSL) | 4192.45 | 4192.69 | 4192.30 | 0.10 |
| LiDAR (Southern GSL) | 4195.98 | NA | NA | NA |
| Difference | 3.53 |  |  |  |
|  |  |  |  | 0.10 |
| Saline <br> (Northern GSL) | 4189.18 | 4189.33 | 4189.02 | NA |
| LiDAR (Northern GSL) | 4192.66 | NA | NA |  |
| Difference | 3.48 |  |  |  |

## Great Salt Lake \& Utah Lake LiDAR 2016

Figure 5.1 Map showing the coverage of the $0.5-\mathrm{m}$ (light blue) and 1-m (dark blue) resolution digital elevation model derived from aircraft LiDAR data collected during the fall of 2016.

A second check of the LiDAR data calibration was performed by comparing the LiDAR data with the USGS bathymetry data collected in 2005 and 2006 when the lake was higher. The results of this comparison are shown in Figure 5.2. Although the LiDAR and bathymetric data for these 25 spot checks are highly correlated with an $R^{2}$ of 0.92 , there is an offset of approximately 4 ft with the LiDAR once again being higher. Thus, this represents a second piece of evidence indicating that that the LiDAR data must be adjusted downward prior to use.

Figure 5.2 Comparison of the LiDAR elevation data with the USGS bathymetric data.

### 5.2 Visible Fines Elevation Distribution

A histogram of the elevation distribution of all locations with visible fines is shown in Figure 5.3. The mean, median, and standard deviation of the distribution are $4201.6 \mathrm{ft}, 4201.0 \mathrm{ft}$, and 3.94 ft , respectively. Thus, $50 \%$ of the locations capable of generating dust plumes if the surface is disturbed are at elevations less than 4201.0 ft . The truncation of the distribution below 4195 ft results from the fact that the lake level fluctuated between 4192.0 and 4195.5 ft during this study (Fig. 2.3).

Figure 5.3 Histogram of the elevations of all the locations with visible fines (VF).

### 5.3 Dust "Hot Spot" Elevation Distributions

A histogram of the elevation distribution of all the GSL dust "hot spots" is shown in Figure 5.4. The mean, median, and standard deviation of the distribution are $4200.9 \mathrm{ft}, 4200.6 \mathrm{ft}$, and 3.43 ft , respectively. Thus, $50 \%$ of the locations currently generating dust plumes under appropriate meteorological conditions are at elevations less than 4200.6 ft . The elevation distribution of the dust "hot spots" differ for the northern and southern portions of the GSL (Fig. 5.5). This figure shows that the dust "hot spots" located in the southern half of the GSL generally occur at a lower elevation than those in the northern half.

Figure 5.4 Histogram of the elevations of all the GSL dust "hot spots".

Figure 5.5 Histograms of the elevations of the GSL dust "hot spots" located in the northern (left) and southern (right) halves of the lake.

### 5.4 Effects of Lake Elevation Fluctuations on the Number of Dust "Hot Spots"

The GSL was divided into four quadrants (i.e., Farmington Bay, Bear River Bay, Gilbert Bay, and Gunnison Bay) to determine how each section of the lakebed responds to fluctuating water levels using a DEM based upon the recalibrated LiDAR data. The results for Farmington Bay are shown in Figure 5.6. This figure shows that $30 \%$ of the dust "hot spots" will be covered by water when the GSL elevation is 4197 ft and that $90 \%$ of the dust "hot spots" will be covered by water when the GSL elevation is 4201.5 ft . The distribution shown in Figure 5.6 is linear with a Pearson correlation coefficient ( $\mathrm{R}^{2}$ ) of 0.9973 . The slope of 0.1383 indicates that a 1-foot increase in the lake elevation will decrease the number of dust "hot spots" by $13.8 \%$ over the range of GSL elevations from 4195.1 ft through 4201.7 ft . Although it is tempting to extrapolate the linear trend beyond the range of the data, it is not advisable. For example, the highest elevation of a dust "hot spot" in Farmington Bay was 4213.5 ft which indicates that the trend does not continue beyond the 0.95 fractional coverage. In addition, nearly the entire area of Farmington Bay is dry when the GSL elevation drops below 4194 ft . As a result, further reductions in lake elevation beyond this threshold level will not expose much more surface area within Farmington Bay.

Figure 5.6 The fraction of dust "hot spots" located in Farmington Bay covered by water as a function of GSL elevation. The uncertainty of the GSL elevation measurements is indicated by the red error bars.

The results of the DEM analysis for Bear River Bay are shown in Figure 5.7. This figure shows that $30 \%$ of the dust "hot spots" will be covered by water when the GSL elevation is 4203 ft and that $90 \%$ of the dust "hot spots" will be covered by water when the GSL elevation is 4206.8 ft . The distribution shown in Figure 5.7 is linear with a Pearson correlation coefficient ( $\mathrm{R}^{2}$ ) of 0.9657 . The slope of 0.1284 indicates that a 1 -foot increase in the lake elevation will decrease the number of dust "hot spots" by $12.8 \%$ over the range of GSL elevations from 4199.5 ft through 4207 ft . Although it is tempting to extrapolate the linear trend beyond the range of the data, it is not advisable. For example, the highest elevation of a dust "hot spot" in Bear River Bay was 4209.4 ft which indicates that the trend does not continue beyond the 0.95 fractional coverage. In addition, nearly the entire area of Bear River Bay is dry when the GSL elevation drops below 4194 ft . As a result, further reductions in lake elevation beyond this threshold level will not expose much more surface area within Bear River Bay.

Figure 5.7 The fraction of dust "hot spots" located in Bear River Bay covered by water as a function of GSL elevation. The uncertainty of the GSL elevation measurements is indicated by the red error bars.

The results of the DEM analysis for Gilbert Bay are shown in Figure 5.8. This figure shows that $30 \%$ of the dust "hot spots" will be covered by water when the GSL elevation is 4198.9 ft and that $90 \%$ of the dust "hot spots" will be covered by water when the GSL elevation is 4203.6 ft . The distribution shown in Figure 5.8 is linear with a Pearson correlation coefficient ( $R^{2}$ ) of 0.9822 . The slope of 0.1167 indicates that a 1 -foot increase in the lake elevation will decrease the number of dust "hot spots" by $11.7 \%$ over the range of GSL elevations from 4196 ft through 4204 ft . Although it is tempting to extrapolate the linear trend beyond the range of the data, it is not advisable. For example, the highest elevation of a dust "hot spot" in Gilbert Bay was 4214.4 ft which indicates that the trend does not continue beyond the 0.90 fractional coverage. In addition, the linear trend starts to break down at the 0.95 fractional coverage. However, unlike Farmington Bay and Bear River Bay, further reductions in the GSL elevation below 4194 ft are likely to follow the same linear trend with regards to the number of dust "hot spots" exposed. The reason for this is that Gilbert Bay still has significant surface area of lakebed to expose if the lake level were to continue dropping.

Figure 5.8 The fraction of dust "hot spots" located in Gilbert Bay covered by water as a function of GSL elevation. The uncertainty of the GSL elevation measurements is indicated by the red error bars.

The results of the DEM analysis for Gunnison Bay are shown in Figure 5.9. This figure shows that $30 \%$ of the dust "hot spots" will be covered by water when the GSL elevation is 4198.7 ft and that $90 \%$ of the dust "hot spots" will be covered by water when the GSL elevation is 4206.9 ft . The distribution shown in Figure 5.9 is linear with a Pearson correlation coefficient $\left(R^{2}\right)$ of 0.9782 . The slope of 0.0726 indicates that a 1 -foot increase in the lake elevation will decrease the number of dust "hot spots" by $7.3 \%$ over the range of GSL elevations from 4196.5 ft through 4208 ft . Although it is tempting to extrapolate the linear trend beyond the range of the data, it is not advisable. For example, the highest elevation of a dust "hot spot" in Gunnison Bay was 4211.8 ft which indicates that the trend does not continue beyond the 0.95 fractional coverage. In addition, the high salt content of the Gunnison Bay has created a thick layer of salt on the bottom of this area of the lake. As the lake level declines below $\sim 4197 \mathrm{ft}$ it exposes this thick layer of salt which is unlikely to produce significant quantities of dust.

Figure 5.9 The fraction of dust "hot spots" located in Gunnison Bay covered by water as a function of GSL elevation. The uncertainty of the GSL elevation measurements is indicated by the red error bars.

### 5.5 Key Findings/Uncertainties

## Key findings

- The number of dust "hot spots" varies linearly with lake elevation as shown in Table 5.2.

Table 5.2 Summary of GSL Elevation Impact on Dust Mitigation.

| Quadrant | 50\% Mitigation <br> Lake Level <br> (feet) | 80\% Mitigation <br> Lake Level <br> (feet) | Slope <br> (\%/foot) |
| :---: | :---: | :---: | :---: |
| Farmington Bay | 4198.3 | 4200.6 | 13.8 |
| Bear River Bay | 4204.2 | 4206.3 | 12.8 |
| Gilbert Bay | 4200.6 | 4202.8 | 11.7 |
| Gunnison Bay | 4201.2 | 4206.2 | 7.3 |

- Farmington Bay is the easiest area to mitigate because it requires the lowest lake elevation to cover the dust "hot spots".
- Bear River Bay is the most difficult area to mitigate because the dust "hot spots" generally occur at higher elevations than the other quadrants.
- The number of dust "hot spots" is unlikely to increase in Farmington Bay, Bear River Bay, and Gunnison Bay if the lake level decreases below 4194 ft because two of these areas (i.e., Farmington Bay and Bear River Bay) already have very little water coverage and the other (i.e., Gunnison Bay) is protected by a thick salt crust.
- The number of dust "hot spots" is likely to increase at a rate of $11.7 \%$ per foot in Gilbert Bay if the lake elevation continues to drop.

## Uncertainties

> This study assumes that all dust "hot spots" produce equal amounts of dust under appropriate meteorological conditions. Further research is required to determine whether the number of dust "hot spots" is a good proxy for total dust production.
$>$ A large calibration adjustment of -3.5 ft was applied to the LiDAR data to force agreement with the measured lake elevation and the bathymetric data. The source of the LIDAR data calibration discrepancy should be investigated.
$>$ The number of dust "hot spots" may change over time due to natural erosion or manual disturbances.

## 6. Have Human Activities Altered the Chemical Composition of GSL Surface Soils?

### 6.1 Results

As a terminal basin lake, the GSL receives both naturally-occurring minerals and anthropogenic pollutants via its tributary streams and direct runoff. The sediment is also influenced by the wet and dry deposition of particulate matter transported from both local and regional sources. Although it is beyond the scope of this project to quantify the relative contribution of natural and anthropogenic sources to the observed $\mathrm{PM}_{10}$ elemental mass fractions, it is possible to use the spatial distributions of these elements (Appendix H) to infer the presence of significant localized sources.

Reviewing the maps contained in Appendix H reveals several broad groupings of elements with similar spatial distributions. More than half of the elements measured in the $\mathrm{PM}_{10}$ soil as part of this project had their peak mass fractions in Bear River Bay. Elements maximized in this region mainly consisted of the major soil elements (e.g., $\mathrm{Si}, \mathrm{Fe}, \mathrm{Al}, \mathrm{Ti}$, and K ) as well as the rare earth metals. An example spatial distribution of the rare earth metals (lanthanum) is shown in Figure 6.1. It is unclear whether the Bear River is a more significant source of these rare earth metals or whether this pattern results from the soil being less salty in this region. Regions of the lakebed with a higher salt content could have an apparently lower concentration in both the major soil elements and the rare earth metals simply due to the displacement by evaporite minerals (i.e., salts). Further analysis of this issue is, therefore, warranted. Bear River Bay also has a high mass fraction of phosphorus (Fig. 6.2) which most likely originates from the runoff of fertilizers into the Bear River.

Farmington Bay is located at the mouth of the Jordan River and has the closest proximity to population centers along the Wasatch Front. As a result, it is one of the most likely regions to be impacted by human activities. Elements with distinctive mass fraction maxima in the Farmington Bay region include: antimony, cadmium, lead, selenium, thallium, uranium, zinc, and zirconium. The spatial distributions of cadmium, lead, and zinc are shown as examples in Figures 6.3 through 6.5. The spatial distribution maps for the remaining elements can be seen in Appendix H.

The southern shore of the GSL near Saltair is immediately adjacent to the Kennecott Utah Copper (KUC) tailings pile. This tailings pile covers ~15 square miles and rises to a height of $\sim 250$ feet above the surrounding terrain. Although KUC employs a wide variety of dust suppression techniques, dust plumes originating from the tailings pile are a common occurrence during high wind events. There is evidence that some of this fugitive dust is deposited onto the adjacent lakebed. For example, copper, molybdenum, and silver all have strong local maxima in the area just north of the tailings pile (Figures 6.6 through 6.8). These elements represent three of the primary metals extracted by KUC. Other elements with local maxima in this region include manganese, nickel, silicon, and sulfur (Appendix H).

Figure 6.1 Map showing the spatial distribution of lanthanum ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure 6.2 Map showing the spatial distribution of phosphorus ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure 6.3 Map showing the spatial distribution of cadmium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

 soil.

Figure 6.5 Map showing the spatial distribution of zinc (mg/kg) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure 6.6 Map showing the spatial distribution of copper ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure 6.7 Map showing the spatial distribution of molybdenum ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure 6.8 Map showing the spatial distribution of silver ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

The coefficient of variation, which is defined as the standard deviation divided by the average concentration, is a statistical term used to describe how large the variations of an element are compared to the average. Table 6.1 shows that the elements with the largest coefficient of variation include copper, sulfur, silver, phosphorus, chlorine, molybdenum, zirconium, and lead. This type of analysis implies that these elements are most likely to have significant local sources which result in a non-uniform spatial distribution. As mentioned previously, copper, molybdenum and silver are enhanced immediately downwind of the KUC tailings pile. The same is true for sulfur (Appendix H). High phosphorus concentrations on the east side of the GSL are most likely associated with fertilizer runoff while high phosphorus concentrations near the Utah Test and Training Range (UTTR) on the west side most likely result from the use of tracer ammunition rounds at the adjacent live-fire range. Zirconium, which also peaks near the UTTR, is a commonly-used component of explosive primers. Thus, there is evidence that military exercises in the UTTR have had a measurable impact on the adjacent lakebed.

Table 6.1 Coefficient of Variation Data Ordered from the Greatest to the Least Variance.

Table 6.1 also shows that the ten most uniformly-distributed elements (i.e., those with the lowest coefficient of variation) include barium, magnesium, uranium, calcium, cobalt, selenium, arsenic, zinc, antimony, and lithium. Recall that two of these elements, arsenic and lithium, had average concentrations which exceeded both the residential and industrial RSLs established by the EPA. The low spatial variation of these elements increases the likelihood that the high concentrations of both arsenic and lithium result from natural, rather than anthropogenic, sources.

### 6.2 Key Findings/Uncertainties

## Key findings

- The elements with the greatest spatial variability include copper, sulfur, silver, phosphorus, chlorine, molybdenum, zirconium, and lead. The high degree of spatial heterogeneity most likely results from anthropogenic sources.
- The area directly north of the KUC tailings pile has high concentrations of copper, silver, molybdenum, sulfur, manganese, nickel, and silicon. The elevated concentrations of these species most likely result from the dry deposition of dust plumes originating from the tailings pile.
- Elevated phosphorus concentrations in Bear River and Farmington Bays most likely result from fertilizer runoff.
- Activities at the UTTR military live-fire range on the western side of the GSL have elevated both the phosphorus and zirconium concentrations in the adjacent lakebed.
- The elements with the most uniform concentrations include barium, magnesium, uranium, calcium, cobalt, selenium, arsenic, zinc, antimony, and lithium

## Uncertainties

$>$ The analysis in this section is neither quantitative nor exhaustive. It is merely intended to qualitatively demonstrate that human activities have influenced the composition of the $\mathrm{PM}_{10}$ soil on the exposed portions of the GSL lakebed.

Appendix D: Maps Showing the Areas of the GSL Playa which Generated Dust Plumes when Manually Disturbed

Figure D. 1 Locations where the boot test produced a visible dust plume (VF) in DU1.

Figure D. 2 Locations where the boot test produced a visible dust plume (VF) in DU2 and DU3.

Figure D. 3 Locations where the boot test produced a visible dust plume (VF) in DU4.

Figure D. 4 Locations where the boot test produced a visible dust plume (VF) in DU5.

Figure D. 5 Locations where the boot test produced a visible dust plume (VF) in DU6 and DU7.

Figure D. 6 Locations where the boot test produced a visible dust plume (VF) in DU8.

Figure D. 7 Locations where the boot test produced a visible dust plume (VF) in the northern half of DU9 and DU10.

Figure D. 8 Locations where the boot test produced a visible dust plume (VF) in the southern half of DU9 and DU10.

Appendix E: Maps Showing the Areas of the GSL Playa where Vegetation was Observed

Figure E. 1 Locations where vegetation was observed (V or SV) in DU1. Red markers indicate that the vegetation occurred in an area where the boot test generated dust plumes from the surface.

Figure E. 2 Locations where vegetation was observed (V or SV) in DU2 and DU3. Red markers indicate that the vegetation occurred in an area where the boot test generated dust plumes from the surface.

Figure E. 3 Locations where vegetation was observed (V or SV) in DU4. Red markers indicate that the vegetation occurred in an area where the boot test generated dust plumes from the surface.

Figure E. 4 Locations where vegetation was observed (V or SV) in DU5. Red markers indicate that the vegetation occurred in an area where the boot test generated dust plumes from the surface.

Figure E. 5 Locations where vegetation was observed (V or SV) in DU6 and DU7. Red markers indicate that the vegetation occurred in an area where the boot test generated dust plumes from the surface.

Figure E. 6 Locations where vegetation was observed (V or SV) in DU8. Red markers indicate that the vegetation occurred in an area where the boot test generated dust plumes from the surface.

Figure E. 7 Locations where vegetation was observed (V or SV) in the northern half of DU9 and DU10. Red markers indicate that the vegetation occurred in an area where the boot test generated dust plumes from the surface.

Figure E. 8 Locations where vegetation was observed (V or SV) in the southern half of DU9 and DU10. Red markers indicate that the vegetation occurred in an area where the boot test generated dust plumes from the surface.

Appendix F: Maps Showing the GSL Dust "Hot Spot"s

Figure F. 1 Dust "hot spot" locations for DU1.

Figure F. 2 Dust "hot spot" locations for DU2 and DU3.

Figure F. 3 Dust "hot spot" locations for DU4.

Figure F. 4 Dust "hot spot" locations for DU5.

Figure F. 5 Dust "hot spot" locations for DU6 and DU7.

Figure F. 6 Dust "hot spot" locations for DU8.

Figure F. 7 Dust "hot spot" locations for the northern half of DU9 and DU10.

Figure F. 8 Dust "hot spot" locations for the southern half of DU9 and DU10.

# Appendix G: $\quad \mathrm{PM}_{10}$ Elemental Mass Fraction Data

${ }^{1}$ - EPA Regional Screening Levels (May 2016) for residential and industrial properties (TR=1E-06, THQ=0.1) cited.
NE - Not Established
BOLD - exceeds the most conservative residential and industrial screening levels.

Appendix H: Maps Showing the Spatial Distributions of the $\mathrm{PM}_{10}$ Soil Elements

Figure H. 1 Map showing the spatial distribution of aluminum ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 2 Map showing the spatial distribution of antimony ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 3 Map showing the spatial distribution of arsenic ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 4 Map showing the spatial distribution of barium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 5 Map showing the spatial distribution of beryllium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 6 Map showing the spatial distribution of boron ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 7 Map showing the spatial distribution of bromine ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 8 Map showing the spatial distribution of cadmium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 9 Map showing the spatial distribution of calcium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

 the soil.

 the soil.

Figure H. 12 Map showing the spatial distribution of chlorine ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 13 Map showing the spatial distribution of chromium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 14 Map showing the spatial distribution of cobalt ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 15 Map showing the spatial distribution of copper $(\mathrm{mg} / \mathrm{kg})$ in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 16 Map showing the spatial distribution of dysprosium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 17 Map showing the spatial distribution of erbium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 18 Map showing the spatial distribution of europium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $P M_{10}$ fraction of the soil.

Figure H. 19 Map showing the spatial distribution of gadolinium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 20 Map showing the spatial distribution of gallium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 21 Map showing the spatial distribution of holmium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

 soil.

Figure H. 23 Map showing the spatial distribution of lanthanum ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

 soil.

Figure H. 25 Map showing the spatial distribution of lithium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 26 Map showing the spatial distribution of lutetium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 27 Map showing the spatial distribution of magnesium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 28 Map showing the spatial distribution of manganese ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 29 Map showing the spatial distribution of molybdenum ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 30 Map showing the spatial distribution of neodymium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 31 Map showing the spatial distribution of nickel ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 32 Map showing the spatial distribution of phosphorus ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 33 Map showing the spatial distribution of potassium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

 fraction of the soil.

Figure H. 35 Map showing the spatial distribution of rubidium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 36 Map showing the spatial distribution of samarium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $P M_{10}$ fraction of the soil.

Figure H. 37 Map showing the spatial distribution of scandium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 38 Map showing the spatial distribution of selenium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 39 Map showing the spatial distribution of silicon ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 40 Map showing the spatial distribution of silver ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 41 Map showing the spatial distribution of sodium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 42 Map showing the spatial distribution of strontium $(\mathrm{mg} / \mathrm{kg})$ in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 43 Map showing the spatial distribution of sulfur ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 44 Map showing the spatial distribution of terbium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 45 Map showing the spatial distribution of thallium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 46 Map showing the spatial distribution of thorium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 47 Map showing the spatial distribution of titanium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 48 Map showing the spatial distribution of uranium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 49 Map showing the spatial distribution of vanadium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 50 Map showing the spatial distribution of ytterbium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 51 Map showing the spatial distribution of yttrium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 52 Map showing the spatial distribution of zinc $(\mathrm{mg} / \mathrm{kg})$ in the $\mathrm{PM}_{10}$ fraction of the soil.

Figure H. 53 Map showing the spatial distribution of zirconium ( $\mathrm{mg} / \mathrm{kg}$ ) in the $\mathrm{PM}_{10}$ fraction of the soil.
